The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health; B.Sc. in Pharmacy; and Ph.D. in the Faculty of Medicine. A Diploma in Public Health (D.P.H.) is also granted.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required after registration as a medical student in the books of the General Medical Council. The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms *specified* in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases Peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

The higher degree of Doctor of Philosophy (Ph.D.) is also conferred in the Faculty of Medicine. Candidates must already have obtained a degree (or equivalent diploma) from an approved University or College and must prosecute a course of special study or research for two or three years and give evidence of satisfactory progress. A thesis must be presented for approval by the Senate on the recommendation of a Special Committee. The candidate may be required to undergo an oral or other examination on the subject-matter of the thesis.

Fees.—The Fees for M.B. and Ch.B. are £34 13s. The class fee in each subject of the curriculum for M.B. and Ch.B. is £3 3s., £4 4s., or £6 6s., and the present fee for hospital attendance is £7. The fee for M.D. is £21, and for Ch.M. £21.

The great majority of the students take their hospital course at the Western, Royal, and Victoria Infirmary, and at the district hospitals of the Glasgow Parish Council, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, Tuberculosis, Insanity, and Electro-diagnosis and Therapeutics. Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it certain medical classes for women are conducted under lecturers appointed by the University Court.

Post-graduate Medical Teaching.—Organised Post-graduate Medical Teaching is available in Glasgow under the auspices of Glasgow Post-Graduate Medical Association. This Association is representative of practically all the Teaching Institutions in Glasgow, and its business is managed by a Board of which the chairman is Principal Sir Donald MacAlister, and the vice-chairman Sir Hector C. Cameron. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. There is a General Medical and Surgical Course, during the last two weeks of August and the first two weeks of September. This is a whole-time course and includes most of the subjects of interest to the general practitioner. The forenoons are occupied with General Medicine and Surgical Diagnosis and Minor Surgery in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in some of the special hospitals or in the special departments of the general hospitals—two subjects each afternoon. On the four Saturday forenoons Tuberculosis and Infectious Fevers are demonstrated at Ruchill Fever Hospital. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Further information may be obtained from Dr. James Carslaw, Secretary.

In this University Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical students who have gone through the Arts course. A full list will be found in the Calendar.

THE ANDERSON COLLEGE OF MEDICINE, Dumbarton-road, Glasgow, W.—Courses are given which qualify for all the licensing boards and for the Universities of Oxford, Cambridge, London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Dental Hospital, Glasgow.

The buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, and adjoining the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students.

Women students are admitted on the same terms as men, and the Carnegie Trust extends its benefactions to students of the College. Full particulars may be obtained from Sir W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, The Anderson College of Medicine, Glasgow, W. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. George C. Pringle, M.A., Educational Institute Office, 47, Moray-place, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Walter Hurst, Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

The Winter Session will open on Oct. 12th, 1925.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—The classes in St. Mungo's College qualify for the medical qualifications of the English. Scotch, and Irish Conjoint Boards, for the dental diplomas of the English, Irish, and Scottish Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. The classes are open to male and female students equally.

The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to £120. Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

QUEEN MARGARET COLLEGE (Women's Department of the University).—This is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curricula, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish University, women students graduated in medicine in Glasgow University; 683 women have now taken the degree of M.B., C.M., or M.B., Ch.B. of the University of Glasgow and 35 the degree of M.D. The women students attend classes in the various University Buildings at Gilmore-hill and Queen Margaret College, the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary. Facilities for clinical work are given in the Royal, Western and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine, and women are admitted to certain University bursaries and fellowships. The Winter Session will open on Oct. 12th.

ROYAL INFIRMARY, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. St. Mungo's College is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, skin, venereal diseases, burns and septic cases. The wards are open to Women Students. At the Outdoor Department the attendances numbered over 200,000. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and 10 house surgeons, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. Post-graduate Classes are held during September in Clinical Medicine, Clinical Surgery, Clinical Gynæcology, Diseases of the Skin, Venereal Disease in the Male, Diseases of the Throat, Nose and Ear, and in Diseases of the Eye. For information regarding fees and other particulars, application should be made to the Superintendent.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds 600. Special wards are set apart for Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, Teeth, Skin, Venereal Disease, and Electro-Therapeutics. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Eighteen resident assistants are appointed annually, without salary, from those who have completed their course. The fees are as follows:—For Infirmary Attendance: (*a*) For Perpetual Ticket, £12 12*s.*; (*b*) for Single Term Ticket, £1 11*s.* 6*d.* For Courses of Instruction: (*a*) Six Months or Two Terms, £5 5*s.*; (*b*) Three Months or One Term, £2 12*s.* 6*d.* A Clinical Laboratory has been opened, and students receive laboratory instruction from the lecturer on clinical methods. Secretary: J. Matheson Johnston, C.A., 87, Union-street.

A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow.—This institution, which was founded in 1882, consists of: (1) a hospital at Yorkhill containing 270 cots built on an elevated and central site close to the University and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a country branch at Drumchapel, Dumbartonshire, containing 30 cots, opened in 1903. Children treated must not be over 13 years of age, nor suffer from infectious diseases. In 1924 there were 6050 in-patients treated, and there were 78,585 attendances of out-patients. There are one professorship and two lectureships in the University of Glasgow in connexion with the hospital, one professorship and one lectureship on the Medical Diseases of Infancy and Childhood, and one lectureship on Surgery and Orthopædics in Relation to Infancy and Childhood. The Professorship is held by Prof. Leonard Findlay, the Visiting Physician, and the lectureships are held one by Dr. Geoffrey B. Fleming, Assistant Visiting Physician, and the other by one of the Visiting Surgeons, Mr. Alex. MacLennan. The lectures are both systematic and clinical, but particularly and chiefly the latter. In addition special facilities are given for post-graduate study. Information with regard to clinical instruction, lectures, and post-graduate study may be obtained from the Medical Superintendent.

GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL, Rottenrow.—The new hospital, which was opened in 1908, is in point of size the largest of its kind in Britain and has accommodation for 114 patients. A Maternity and Child Welfare Centre has been established in connexion with the hospital, consisting of a complete In-door and Out-door Ante-natal Department and an Infant Consultation Clinic. In 1924 4071 normal cases and 2088 abnormal cases were treated by the hospital in the In-door and Out-door Departments. Secretary: Mr. William Guy, 146, Buchanan-street. Full particulars as to fees and accommodation may be obtained from the House Superintendent at the hospital.

ROYAL SAMARITAN HOSPITAL FOR WOMEN, Glasgow.—This hospital, founded in 1886, is the largest purely gynæcological hospital in Great Britain, possessing as it does, 90 beds, which will be increased to 160 when building extensions are completed. It offers excellent facilities for clinical instruction in the diseases peculiar to women, treating in the wards and in the out-patient department from 5000 to 6000 cases per annum. Lectures and clinical demonstrations are given by members of the surgical staff to students and to post-graduates; and the hospital is represented on the Board of the Glasgow Post-Graduate Medical Association formed for co-ordinating post-graduate medical teaching in all the hospitals. For further information application may be made at the Hospital, or to T. Mason Macquaker, M.A., B.L., Secretary, 149, St. Vincent-street, Glasgow.

GLASGOW LOCK HOSPITAL, 41, Rottenrow, Glasgow. This hospital was founded in 1805 for the treatment of females suffering from Venereal Diseases. It contains 80 beds. There is also a Labour Ward, and a well-equipped Dispensary for out-patient attendances. There is now a Lecture Room and Laboratory, equipped with the most modern appliances, which has been building during the past year, and has just been completed for the accommodation of Students who receive their clinical instruction there. The number of students attending these classes in 1924 was 176; Post-graduate classes are also held. During the course of the past year the hospital has been completely renovated and modernised. In 1924 there were 424 in-patients, and 17,698 attendances were made by out-patients at the Dispensary. The Secretary and Treasurer is Mr. J. Neilson Gray, LL.B., 65, Bath-street, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street, and 131, Wellington-street (30 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 919; out- or dispensary patients, 15,424; daily average of attendances, 147; total attendances, 44,988. Operations on Wednesdays and Fridays. This institution is administered by the Royal Infirmary. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 26,010 and the total number of cases in 1924 was 65,566. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine, and by the Royal Colleges of Physicians and Surgeons of England for the Diploma in Ophthalmic Medicine and Surgery. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Secretary and Acting Treasurer: Harold John Black, 88, West Regent-street, Glasgow. The medical session opens in October. Post-graduate Classes are being held.

GLASGOW HOSPITAL FOR DISEASES OF THE EAR, NOSE, AND THROAT, 27 and 28, Elmbank-crescent.—15 beds. New patients, 6732. Attendances at out-patient department, 21,550. Admitted to in-door department, 433. Clinical instruction is given in connexion with Dr. Connal's course on Diseases of the Ear at Anderson's College and Dr. Syme's course on Diseases of the Throat and Nose at the Western Medical School. Secretary: D. N. Mackay, 144, St. Vincent-street, Glasgow.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), a Diploma in Public Health, and Diploma in Dental Surgery (L.D.S.).

The Preliminary Examination includes (a) English, (b) Latin, (c) Elementary Mathematics, and (d) one of the following optional subjects: (α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other approved modern language. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of L.L.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—A pre-registration examination is held in Physics and Chemistry. Candidates must have been engaged in medical study for at least five years after registering as a medical student. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Bacteriology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica, Pathology and Bacteriology, Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical). The combined fee for tuition and clinical tuition is £182, payable in five annual instalments. Additional fees are required for hospital ticket, midwifery cases, laboratory apparatus.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 33 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University

Court. The fee to be paid for the degree of Doctor of Medicine shall be 20 guineas, and for the degree of Master of Surgery 20 guineas. The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St. Andrews. For further particulars and details as to scholarships and bursaries application should be made to Prof. Charteris, Dean of the Medical Faculty, University College, Dundee.

UNIVERSITY COLLEGE, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the medical buildings there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

ROYAL INFIRMARY, Dundee.—The Infirmary contains 401 beds. In addition to the ordinary Medical and Surgical Wards, there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose and Throat, and of the Skin; and for Clinical Pathology, Radiology, Electro-therapeusis, and Electro-cardiography. An extension providing for new X Ray and Massage Departments and for additional Operation Theatre accommodation has been opened this year at a cost of £25,000. Clinical teaching is given to male and female Students by the Honorary Staff; post-mortem examinations are conducted by the pathologists. All courses of instruction are recognised by the University of St. Andrews and the other Boards of the United Kingdom. Nine Resident Medical Officers are appointed every six months. Clinical clerks and dressers are attached to the Physicians and Surgeons; and Students are appointed as assistants in the pathological department. The fees for Hospital attendance are as follows: For Perpetual Ticket, £12, or if paid in instalments, £12 12*s.*; Ticket for 12 Months, £4 4*s.*; Ticket for 3 Months, £1 11*s.* 6*d.* Further information may be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., Doctor of Medicine (M.D.), *Master of Surgery* (Ch.M.), Bachelor of Medicine (M.B.), and Bachelor of Surgery (Ch.B.). The Degree of Doctor of Philosophy (Ph.D.) is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Before commencing his medical studies each student must comply with the following regulations: (1) Every Candidate desiring admission to the Faculty of Medicine must be in possession of the necessary "Certificate of Fitness" issued and attested by the Scottish Universities Entrance Board, 81, North-street, St. Andrews. Forms on which to make application for this Certificate may be obtained from the Secretary to the University of Aberdeen. From and after Jan. 1st, 1921, the Regulations contained in the Ordinances for Degrees in Medicine are revoked, and the following General Regulation made by the Entrance Board is substituted therefor, namely: "That (*a*) the Group Certificates of the Scottish Education Department, or (*b*) the evidence of satisfactory completion in Schools in Scotland of a curriculum of Secondary Education, as attested by the said Group Certificates or otherwise, or (*c*) the Leaving or other Certificates accepted as qualifying for admission to the Universities in the case of applicants for admission from outside Scotland, which shall be deemed to entitle applicants for admission to the Universities to enter upon a course of study qualifying for graduation in the Faculty of Medicine, shall be the same as those which, under the Regulations for the time being in force, are deemed to entitle applicants for admission to the Universities to enter upon a course of study qualifying for graduation in the Faculty of Arts or, alternatively, in the Faculty of Science, for Degrees in Pure Science."

Candidates, therefore, before entering on the curriculum for the Degree must: (1) have passed (*a*) the Arts Preliminary Examination, or (*b*) the Science Preliminary Examination, or (2) hold a qualification recognised as exempting from such examination. (3) Have attained the age of 17 years. (4) That they have passed the Pre-registration Examination in Physics and Chemistry.

Regulations for Pre-registration Courses in Physics and Chemistry have been made by the University in accordance with which the appropriate exemptions can be granted to students.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital; they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

The cost, including Matriculation, Class, Degree, and Hospital Fees, for the whole curriculum leading to the Degrees of M.B. and Ch.B. is approximately £240.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institutions, &c.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

Degree of Ph.D.—For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto. A Thesis must be presented for approval. The fee is £10 10*s.*

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Application for further information should be addressed to the Secretary of the Medical Faculty.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years. Scholarships: five Post-Graduate Scholarships, value £36 to £160 per annum. Prizes and Medals: 18 Gold Medals and Prizes for proficiency in special departments, &c.

Clinical Instruction is given in the Aberdeen Royal Infirmary (270 beds) by the physicians and surgeons on the staff.

ABERDEEN ROYAL MENTAL HOSPITAL.—Contains, with hospital attached to main institution and agricultural branch, about 950 beds. Clinical instruction is given to students during three months in summer. Clerk and Treasurer, Mr. A. Scott Finnie, 318, Union-street, Aberdeen.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

SCOTTISH CONJOINT BOARD.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months; Anatomy, during at least six months; Practical Anatomy, twelve months; Physiology, six months; Practical Physiology, three months; Materia Medica, three months; Pathology (including Practical Pathology), nine months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery, three months; Gynæcology, one course of not less than 13 meetings; Diseases of Children, one course of not less than 13 meetings; Medical Jurisprudence and Public Health, three months. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital. This attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months: Gynæcology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Physics, Chemistry, and Elementary Biology.

Second Examination includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

Third Examination includes Pathology and Materia Medica with Pharmacology.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women; and, if not passed previously, Medical Jurisprudence and Public Health, but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time; but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c. The fees payable for the Final Examination shall be—for the whole examination, £15, for re-entry after rejection, £5, and for the subjects of Medical Jurisprudence and Public Health when taken separately, £5, with £3 for re-entry in that subject.

There are four periods of examination annually: During the ensuing period twice in Edinburgh and twice in Glasgow, in 1925–26. The Registrar in Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom particulars of fees can be obtained.

For students registered with the General Medical Council after Jan. 1st, 1923, more extensive Regulations are in force, and candidates applying for Regulations should state date of registration.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship.*

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence. The fee for the Membership is £36 15*s*., 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship.—The Fellows are selected from the ranks of the *Members.* The fee is £64 18*s*.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH: THE FELLOWSHIP.

The Royal College of Surgeons of Edinburgh also admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of

Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and also to the Fellowship, and the regulations apply to practitioners of either sex.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees or diplomas of such British examining bodies, as well as of the holders of such surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire as are recognised by the College.

The Fellowship.—Candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly vivâ voce, and must include surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. The fee to be paid on entering for examination for Fellowship is £45, £10 of which is remitted to those who already hold the Licentiateship of the College. Candidates rejected at the examination obtain repayment of fee less £10 retained for examination expenses. One month's notice of intention to appear for examination must be given by the candidate to Mr. D. L. Eadie, 49, Lauriston-place, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, otherwise a special application, with six testimonials, must be made to the President and the Council of the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held separately.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate of his intention to present himself to Mr. Walter Hurst, the Faculty Hall, 242, St. Vincent-street, Glasgow. The fee for the Fellowship is £50, £10 of which sum is returned to any successful candidate who already holds the Licence of the Faculty. In certain circumstances Fellows may be elected as a mark of distinction.

Licence.—The Licence of the Royal Faculty is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

SCOTTISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

The hospitals which are recognised by the Scottish Conjoint Board as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities. In addition the Scottish Boards recognise all the places which are recognised by the English Conjoint Board (see p. 431) and the Irish Conjoint Board (see p. 455).

III.—IRELAND.

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—In order to join the School of Physic students pass a matriculation examination. University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council. The winter courses begin on Oct. 1st.

Pre-registration Examination in Elementary Physics and Chemistry.—Before beginning the five years' Medical curriculum students must pass an examination in elementary Physics and Chemistry. This examination is held at the end of September, in January, in March, and in June. Courses in preparation for it may be taken in the School of Physic. On passing this examination Medical students should register as such with the General Medical Council.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of registration. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Botany, Zoology, Physics and Practical Physics; Systematic, Descriptive and Applied Anatomy; Chemistry and Practical Chemistry; Histology, Physiology, Practical and Applied Physiology; Practice of Medicine; Midwifery and Gynæcology, Pathology and Bacteriology; Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Surgery and Operative Surgery; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 20 personally conducted cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy, Physiology, and Organic Chemistry; and Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica and Therapeutics, Hygiene and Jurisprudence, Pathology and Bacteriology; and Part II., Medicine, including Clinical Medicine and Mental Diseases; Surgery, including Operative and Ophthalmic Surgery; Midwifery and Gynæcology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also submit a thesis and pass an Examination before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing and must produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital or other recognised institution, a six months' course in Trinity College, and then pass a special examination. Three months of these courses may be taken concurrently.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Post-graduate Instruction.—Arrangements have been made, with the approval of the Board of Trinity College, for a post-graduate course of instruction at the School of Physic during the autumn from Monday, Sept. 14th, to Saturday, Oct. 3rd. Members of the class can reside in college rooms and dine on commons.

Clinical Instruction.—The hospital facilities for clinical instruction available in Dublin will be described below.

NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students intending to proceed to the medical degree of the University of Ireland must pass a matriculation examination, the examination taking place in June and September in Dublin and at certain local centres. All students must pass in five subjects (three of which must be Irish, English, and mathematics). All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—1. Irish. 2. Latin or Greek. 3. French, German, Italian, Spanish, Portuguese, Welsh, or any other modern language approved by the Senate. 4. English. 5. Mathematics. 6. Latin, Greek, French, German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate, History, Geography, Applied Mathematics, or Physics as an alternative, Chemistry, Botany, and for women candidates only, Physiology and Hygiene. Candidates who under the regulations are exempted from the necessity of presenting Irish as one of their subjects, may present as their fifth subject either a second language or a second science subject. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, may be accepted as matriculated students of the Faculty of Medicine on passing the matriculation examination in any faculty.

The medical degrees granted are:—

M.B., B.Ch., and B.A.O.; and M.D., M.Ch., and M.A.O., Ph.D.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN.—The University and the College were created by the Irish University Act, 1908, and by Charters issued in December, 1908. Former students of the Cecilia-street School of Medicine who graduated in the Royal University may become graduate members of the new College. The constitution of the College, like that of the Constituent Colleges of Cork and Galway, provides for a governing body, an academic council consisting of professors and coöpted lecturers, a body of graduate members, and a body of student members matriculated in the University. The first professors were appointed by the Dublin Commissioners Irish Universities Act, 1908.

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland.

Universities Examinations in Medicine.—The First Examination includes Applied Physics, Applied Chemistry, Botany, Zoology, and Applied Biology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination includes Pathology, Medical Jurisprudence and Hygiene, and Materia Medica.

Degrees of M.B., B.Ch., and B.A.O.—The Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year when the curriculum has been completed. The course of study is as follows:—First year.—Winter: Anatomy and Practical Anatomy (required for the Second Examination), Applied Chemistry, Materia Medica and Pharmacology, Applied Anatomy and Physiology, Practical and Applied Physics (with Laboratory Course). Summer: In addition, Applied Biology, Anatomy, and Physiology. Second Year.—Winter: Anatomy, Practical Anatomy, Physiology, and Practical Physiology (physical and chemical). Summer: Anatomy, Practical Anatomy, Physiology, and Practical Histology. Third year.—Winter: Pathology, Surgery, Materia Medica and Pharmacology, Applied Anatomy and Physiology, and Pharmacy. Summer: Materia Medica and Therapeutics, and Practical Pathology. Candidates are also required to attend a General Hospital for nine months (winter and summer). Fourth year, or fourth and fifth years.—Medicine, Medical Jurisprudence and Hygiene, Midwifery and Gynæcology, Operative Surgery, Therapeutics, Applied Anatomy, and Ophthalmology and Otology. Candidates are also required to attend a General Hospital for nine months (winter and summer), to take instruction in Vaccination, and three months Fever Hospital. Fifth year.—If the Academic (Collegiate) Courses are taken as above, the Courses of the fifth year will be the following: Hospital Attendance, General Hospital, nine months; Clinical Ophthalmology and Otology, three months; Practical Midwifery and Gynæcology, six months; Mental Diseases, to be attended at a Lunatic Asylum, three months. (*Note.*—Practical Midwifery and Gynæcology may be taken in the fourth year after the Systematic Course of Midwifery, but it must not be taken concurrently with the period of attendance at Fever Hospital.) Hospital attendance on Diseases of the Skin, Children's Diseases, Diseases of the Ear, Throat and Nose, Venereal Diseases, and instruction in Radiology are also included in the new curriculum. The degree of M.D. may be obtained either by examination or on published work.

Fees.—The fees for Courses may be obtained on application to the Registrar for the College publications. Information concerning these, and the scholarships and exhibitions of the College can be obtained from the Dean of the Faculty, Prof. E. P. McLoughlin.

UNIVERSITY COLLEGE, CORK: THE SCHOOL OF MEDICINE.—The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs, the last of these holding a public meeting yearly in the Mardyke grounds.

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students. Students who are candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination recognised by the General Medical Council. For information as to the conditions and courses of the Matriculation Examination application may be made to the Registrar, National University, Dublin.

Admission of Medical Students.—Students in the Faculty of Medicine who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination. Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may rank as fourth-year.

Residence of Students.—There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary. All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, Fever, the District, and Ear, Eye, and Throat Hospitals.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, Professor A. E. Moore.

*South Charitable Infirmary and County of Cork General Hospital** (100 beds).—Clinical instruction is given daily in the wards. Special instruction on Diseases of Women and Children will be given in the special wards for such cases. Fee for nine months, £12 12*s.*; for six months, £8 8*s.*; for three months, £4 4*s.* Two resident pupils will be appointed by competitive examination.

Cork North Charitable Infirmary and County and City of Cork General Hospital (112 beds).—Clinical instruction is given daily in the wards by the physicians and surgeons. Special instruction is given to Junior students on two days weekly. Fee for 12 or nine months, £12; for six months, £8; and for three months, £4. Three resident pupils are appointed quarterly by the medical staff. All resident pupils are required to be registered pupils of the hospital. There is a special department for treatment of the eye, ear, throat, and nose, and a special dental department. The hospital contains a fully equipped Pathological Department, and a large and extensive X ray Department has recently been added.

Mercy Hospital.—Clinical hospital recognised by the General Nursing Council for Ireland. This hospital contains 130 beds for medical and surgical cases. There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat. Extern medical and surgical, also eye, ear, and throat attendances for 1924, 20,217; intern patients, 1924, 1604. Daily average, 87. Two resident students. Honorary Secretary to the Staff: Dr. D. J. O'Connor. Special apartments for nurses and nuns under training.

Cork Mental Hospital (Psychological Medicine).—A course of Clinical Lectures on Mental Diseases and Allied Neuroses will be delivered by the Resident Medical Superintendent in the Cork Mental Hospital as soon as possible after the opening of the Trinity Term. The lectures will comprise: Normal Psychology; Psychology of the Insane; Psychoses, Statistics, Classification, Ætiology, Symptomatology, Diagnosis, Prognosis, Pathology and Treatment; Psychoneuroses; Neuroses; Psycho-Analysis. The course will be illustrated by typical cases. For further particulars apply to Dr. Owen F. McCarthy, Resident Medical Superintendent.

Victoria Hospital (Incorporated) (Cork).—There are 75 beds. Clinical instruction on Diseases Peculiar to Children is given. The extern department is open daily at 9.30.

County and City of Cork Lying-in Hospital (Erinville, Western-road; founded 1798).—This hospital contains 22 beds, an Extern Midwifery Department, Gynæcological Department, Extern Department for Women, and Child Welfare Centre. Training Centre for Midwives, preparing for C.M.B. examinations. Fee for six months' attendance, including clinical lectures, £5 5*s.* For further particulars apply to Lucy E. Smith, M.D., secretary to staff.

Cork Maternity (Batchelor's Quay).—Three resident pupils are taken into the Maternity. Poor women are attended at their own homes and there are 8 intern beds. A Child Welfare Centre and Clinic was established in 1919. Clinical lectures are delivered during the session. There is an extern department for the treatment of women's and children's diseases. Fee for attendance at clinical lectures and certificate £5 5*s.* Honorary secretary to staff (*vacant*).

Cork Fever Hospital.—Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital. The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh.

---

* No returns.

*Cork District Hospital** (Douglas-road: 1200 beds). This hospital includes special buildings for fever and other infectious diseases (100 beds); for children's diseases (100 beds); and a Lock hospital, the only one in the South of Ireland (80 beds). It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynæcology and diseases of the skin and nervous system. The physicians and surgeons visit the hospitals every morning at 10 o'clock. Lectures and clinical instruction are given daily in the wards by the physicians and surgeons. Further particulars may be obtained from Dr. D. Morrissy, 88, South Mall, Cork, honorary secretary, medical staff.

Cork Eye, Ear, and Throat Hospital (Western-road). This hospital is open to students attending the University College and others. Certificates of attendance for three or six months can be obtained. The hospital contains 35 beds. Over 3000 cases are treated during the year. A course of lectures is delivered during the session; also a post-graduate course of instruction. For further information apply to Dr. Arthur Sandford, Eye, Ear and Throat Hospital.

University College, Galway: School of Medicine.—The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £20 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value £20 each, are reserved for Medical Students. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Central Tuberculosis Hospital and in the Galway Central and Fever Hospitals, containing on an average 270 patients.

Central Hospital, Galway. 300 beds.—This Hospital has been completely built and in working condition. In addition to the Surgical and Medical Departments there are now available: Eye and Ear, Throat and Nose, Gynæcological and Obstetrical, Pathological, X ray and Electrical and Massage Departments as well. Students attend from University College, Galway. Medical and Surgical Clinics are held on alternate days during term. One Resident Physician and one Resident Surgeon are appointed every six months. Four resident students are appointed every quarter. The Hospital is open to qualified medical men for Post-graduate work.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance Examination of any other University or College approved for that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the First Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for

---

* No returns.

Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has passed in the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory. —In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical Instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum.

Royal Victoria Hospital, Belfast (850 beds).—Students eligible for McGrath, McQuitty, Malcolm, Coulter and Smyth Scholarships aggregate annual value £185. Ten House Surgeons and House Physicians. 30 resident pupilships, three months each, annually for Senior Students, of which a proportion is allotted to Women Students. Special Departments for Radiology, Clinical Pathology, V.D., Dermatology, Gynæcology, Vaccine Therapy, Electrocardiography, Dentistry.

Mater Infirmorum Hospital[*] (270 beds).

Belfast Infirmary and Hospital (1600 beds).—Clinical courses are given quarterly, and a course for D.P.H. in Hospital. Intern Venereal Clinic in Infirmary under Corporation scheme. Maternity Hospital recognised for Practical Midwifery training. Particulars may be obtained on application, as to classes, to Dr. McLiesh. Certificate of vaccination class recognised by Local Government Board. A new department for Cancer with 32 beds has been opened.

Belfast Hospital for Sick Children, Queen-street.—Clinical instruction is given in this hospital. During the Winter Session two Courses of Lectures are delivered on the Medical and Surgical Diseases incidental to Infancy and Childhood. Demonstrations in Ophthalmology and Pathology are given, and ample opportunities are afforded in the wards (which contain 45 beds), and in the Out-patient Department, which is largely attended, for gaining a practical and theoretical knowledge of the diseases of Infancy and Childhood. This Hospital grants Certificates in Diseases of Children, which are recognised by the various Examining Bodies. A Gold Medal is offered for competition at the close of the session. Fee for the session—2 guineas. For re-attendance—1 guinea. Hon. Secretary to the Medical Staff, Dr. Rowland Hill.

Maternity Hospital, Townsend-street, Belfast.—Twenty-five beds in constant occupation, and exclusively devoted to Midwifery and Antenatal conditions. There is also a large district. The Queen's University of Belfast have erected a Students' Hostel in connexion with the Hospital where six Students and Post-graduates are received each month. The University Tutor in Obstetrics resides in the Hostel and Students conduct their cases under his supervision. There is a large Antenatal Department and a Department for Venereal Diseases. The Hon. Secretary of the Medical Staff is T. S. S. Holmes, F.R.C.S.

Ulster Hospital for Children and Women, Templemore-avenue, Belfast (52 beds).—Clinical instruction to students in Diseases of Children, Gynæcology and Obstetrics. Special departments: Radiology, Eye, Ear, and Throat, and V.D. Clinic. Gold Medal awarded annually. One House Surgeon appointed from students of hospital.

Benn Ulster Eye, Ear and Throat Hospital, Incorporated, Clifton-street, Belfast (30 beds).

Belfast Ophthalmic Hospital, Great Victoria-street (30 beds).—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, and Laryngology. Clinical instruction is given daily.

Belfast Fever Hospitals.—City Fever Hospital, Purdysburn (300 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-Graduate (D.P.H.) Classes are also held. Lecturer: A. Gardner Robb, M.B., D.P.H.

Belfast Mental Hospital (*Purdysburn Villa Colony*) (1000 beds).

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

---

[*] No returns.

The Membership.—Examinations for Membership are held in February, June, and November. The fee for the examination is £21 to Licentiates of the College, or £36 15*s.* to non-Licentiates.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years. There is a fee of £35 in addition to a stamp duty of £25.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an Examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the Examination.

Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery.

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars as to fees and conditions of examination can be obtained from the Registrar of the College, Stephen's-green West, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

Professional Examinations.—There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognised medical schools at home and abroad. The first examination deals with (*a*) Anatomy, and (*b*) Physiology and Histology. The second examination deals with (*a*) Pathology, (*b*) Materia Medica, Pharmacy, and Therapeutics and Ophthalmology, and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (*a*) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (*b*) Surgery, including Operative Surgery; (*c*) Midwifery, including Diseases of Women and Children, and the Practice of Vaccination.

Fees.—Preliminary Examination, £2 2*s.*; Re-examination, £2 2*s.* Pre-Registration Examination, £3 3*s.* Re-examination in Chemistry, £2 2*s.*; in Physics, £1 1*s.* First Professional Examination, £15 15*s.*; Second, £15 15*s.*; Final, £6 6*s.* Re-examination fee is £2 2*s.* for each division.

Diploma in Psychological Medicine.—There are two examinations in connexion with this Diploma: Part I. consists of (*a*) Anatomy and Physiology of the Nervous System; (*b*) Psychology. Part II.: (*a*) Neurology, including Clinical and Pathological Neurology; (*b*) Psychological Medicine, including its legal relationships.

Fees.—£3 3*s.* for each part.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green.

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5*s.*; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green W., Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Hall entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence.

Candidates must pass two Professional Examinations, called the *Primary Examination and* the Final Examination, which are conducted at separate times, partly in writing, and partly practically and orally. The Primary and Final Professional Examinations are held twice a year—viz., in June and November, or such other dates as may be determined. The Fees payable for each Examination are as follows: Primary Professional, £21; Final Examination, £21.

Candidates who produce satisfactory evidence of having passed an examination for a Degree or *Licence* in Medicine, conducted by any University in the British Empire, or by the Royal *Colleges of Physicians* and Surgeons of Ireland or Great Britain, or by any Foreign University whose Degrees are recognised by the General Medical Council for purposes of Regulation in the Foreign List of the Medical Register, will be exempted from further examination in such subject or subjects of the Primary Examination.

The subjects for Part I. of the Primary Examination are: Anatomy, Physiology and Histology, including Bio-Chemistry; and for Part II., Materia Medica and Pharmacy, Pathology, and Medical Jurisprudence and Hygiene.

For the Final Examination the subjects are: (a) Medicine and Clinical Medicine and Clinical Methods. (b) Surgery—Clinical, Ophthalmic and Operative; and Surgical Anatomy. (c) Midwifery and Gynæcology, and Practical Pharmacy and Materia Medica (if not taken at Intermediate Examination).

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied by the Registrar at 96, Merrion-square, Dublin.

HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.[1]

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street Dublin.—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Ten Resident Pupils are appointed every four months. Twelve surgical Dressers and twelve Clinical Clerks are appointed each month. There are facilities for women students.

Prizes and Medals.—Clinical medals and prizes amounting to about £21 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

Fees.—Winter and summer session, £12 12s.; winter session (six months), £8 8s.; and summer session (three months), £5 5s. Special certificate in anæsthetics, £1 1s. The practice of this hospital is open to all students, and the certificates are recognised by Dublin University, the National University and Royal Colleges of Surgeons of England, Ireland, and Scotland.

The Hospital is an official "Treatment Centre" for venereal diseases.

Further information will be supplied by the Hon. Secretary to the Medical Board.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this Dispensary. A deep therapy X ray apparatus has been installed for the treatment of malignant cases. There is accommodation for intern pupils who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. The residents' quarters are comfortable. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Fees: Extern pupils for full course of six months, £8 8s.; three months, £4 4s. Intern pupils, one month, £4 4s.; each consecutive month, £3 3s.; six months, £18 18s. Registration fee, in advance, 10s. 6d. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the Hospital.

ADELAIDE HOSPITAL, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12s.; six months, £8 8s. Summer, three months, £5 5s.[2] Two resident surgeons are elected half-yearly and four or more resident pupils every four months. At the termination of the session prizes in Clinical Medicine, in Surgery, in Gynæcology, and in Dermatology will be awarded.

Wallace Beatty Memorial bursaries will be awarded at the commencement of the winter session.

Hudson Scholarship.—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Dr. L. G. Gunn.

JERVIS-STREET HOSPITAL, Dublin.—Founded 1718; rebuilt 1886. 130 beds. The operation theatre contains all modern requirements.

MATER MISERICORDIÆ HOSPITAL, Dublin. (Under the care of the Sisters of Mercy.)—This Hospital was founded in 1861 by the Sisters of Mercy. It is the largest in Ireland, containing 382 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical operations will be performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents; a fully-equipped Biochemical Laboratory, a modern Electro-Massage Department, and Electro-cardiograph room. Instruction will be given on Pathology and Bacteriology. Three House Physicians, eight House Surgeons, and 27 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases; also a Training School and a Home for Trained Nurses in connexion with the Hospital. Trained and experienced Nurses who have passed a qualifying examination in nursing can be obtained on application to the Lady Superior, Mater Misericordiæ Hospital.

Terms of attendance.—Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s. Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. John O'Donnell, 3, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Medical Board, Mr. H. Barniville, 9, Merrion-square.

---

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in some of the Irish centres have been described.

[2] Special Lectures in Dermatology are given weekly; also practical demonstrations on the treatment of fractures from time to time.

Meath Hospital and County Dublin Infirmary. This hospital was founded in 1753 and now contains 150 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical Clinical Clerks and Surgical Resident Pupils and Dressers are appointed every three months, and two House Surgeons and a Resident Casualty Officer are elected twice annually. Apply to Hon. Secretary and Treasurer of the Medical Board.

Mercer's Hospital.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large dispensary for out-patients and a modern X ray department. An electro-cardiograph has been installed. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. A gold medal is awarded annually to the best student. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from amongst deserving members of the class.

Fees.—Winter, six months, £8 8*s.*; Summer, three months, £5 5*s.*; nine months, £12 12*s.*

For further particulars apply to Dr. Bethel Solomons, Hon. Sec., Medical Board, 42, Fitzwilliam-square.

National Maternity Hospital, Holles-street, Dublin.—Established 1894. The hospital consists of an Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children. During the year 1924–25, 1306 cases were admitted; 791 confinements took place in the hospital, and 349 gynæcological operations were performed. 4436 applied for treatment at the Dispensary. Every facility is given for the carrying out of practical work. Post-graduate and special courses are arranged for at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Terms.—Intern Pupils: Six months, 10 guineas; three months, 9 guineas; two months, 6 guineas; one month, 3 guineas. Extern Pupils: Certified Courses (three months), 6 guineas; Post-graduate Courses by special arrangement. Clinical Lectures are given daily and Oral Lectures four times per week. During the past year over 90 Post-graduate students were admitted. The L.M. Diploma is given by special examination, which is held three times a year. Further particulars can be obtained from the Master, Dr. Patrick McArdle, 27, Merrion-square; or from the Secretary, Holles-street, Dublin.

Richmond, Whitworth, and Hardwicke Hospitals (House of Industry Hospitals), Dublin.*—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 20 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced students but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. Women students are eligible for election as residents and special apartments are reserved for their use. For prospectuses apply to Mr. Adams McConnell, F.R.C.S.I., Hon. Secretary, 69, Fitzwilliam-square, Dublin.

Rotunda Hospital, Dublin.—This institution is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually and 500 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year and consists of daily clinical instruction in the maternity department and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M. and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6*s.*, months other than the first £4 4*s.*, three months £12 12*s.*, six months £21. For further particulars apply to the Master, Dr. Gibbon FitzGibbon.

Royal City of Dublin Hospital.—Founded 1832; enlarged 1851; rebuilt 1893. 135 beds. There is a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. Secretary: W. H. Leadbeater.

Royal Victoria Eye and Ear Hospital, Dublin. —Established 1844. Incorporated 1897. 102 beds. In-patients, 1499; out-patients, 8492.

Dr. Steevens' Hospital, Dublin (Kingsbridge).—Established 1720. 250 beds, only 150 now in use. Patients, intern, 1300; extern dispensary attendances, including special V.D. Clinic, 38,470. There is accommodation for 12 Resident Pupils, each of whom is provided with a separate bedroom, and board is supplied by the Hospital, at a reasonable rate. All information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital. Secretary: E. D. F. Banks.

St. Vincent's Hospital and Dispensary, *Dublin.** —Established 1834. 200 beds. *Clinical Lectures* in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for Senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Farrell gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the Surgeon McArdle Prize, value £20. In the coming term there will be opened a New Extern Department and a New Pathological Laboratory. Dr. Meenan, hon. secretary, 28, Fitzwilliam-square.

* No returns.

We take this opportunity of thanking the officials of Government Departments and the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

MEDICINE AND THE BUSINESS ASPECT.

THE medical schools throughout the kingdom will be starting the new professional year within the next few weeks, and our present issue, as has been usual at this season, gives a description of these schools, as well as a summary of the curriculum which takes into consideration the various university faculties and corporations entrusted by law with the examination of the students. The number of new students, it would seem, is quite adequate, neither is there any difficulty being experienced in the obtaining of recruits, nor is there now the risk that the medical profession may become overcrowded, as the figures of some five years ago certainly suggested. A dramatic rearrangement of entries, however, is being prophesied from Ireland in response to the action of the Government of the Free State, from whom an unexpected decision has been announced that a separate medical register for the State will be set up. The position was outlined in brief last week, and the suggestion that the move would be unpopular with the medical profession, and especially with the educational authorities in the Free State, has received ample confirmation. From one point of view the action of the Irish Free State is logical. The ideal of the State is independence wherever possible, and the appearance of allegiance to the General Medical Council, whose sessions take place in London, seemed to conflict with the ideal. To those, however, who appreciate the all-embracing hopes of modern medicine, an ideal founded even on such broad grounds as national aspirations will never seem sufficient. There is no possibility of limiting the influence of disease, save in matters of detail, by race or geography, and similarly there is no possibility of adjusting the pattern of medical education or the standards of ethical conduct in accordance with a colour scheme on a map. There is no reason why the Government of the Free State should not be able to evolve an adequate scheme of registration for their country, under which educational facilities are properly coded and bad manners or morals are duly penalised. When this position is reached reciprocity in a certain measure with other countries will follow, but it cannot be reached in a few weeks in response to legislative enactment. Meantime South Irish students may be seeking to obtain their training and their professional qualifications at centres where passing the tests will result in their names being placed on the general Medical Register.

When the schools are formally opened in October the students will in many places be addressed by some person in a position of authority upon the prospects that open out before them. The time has gone by when these introductory addresses were always delivered by a senior member of the teaching staff, and along one line—that of exhortation to the student, who was congratulated upon his choice of a career, to be industrious and enthusiastic in his studies, and to expect to receive material rewards little proportionate to the virtues expended. Such addresses conveyed some truth but concealed one fallacy. Looking steadily at the noble side of our calling, the orators would omit to take notice of the fact that that calling has also its business aspect, for hardly one of them was ever found mentioning that in the successful conduct of a business life it is as well to understand the relations in which that life stands to the social scheme in general. The matter is brought forward now in the hope that it may inspire some of those who are to address the students at the opening of the forthcoming session to remind the audiences that their professional duties will have always to be conducted with reference to the public; their responsibilities will be immediately towards their patients, but these responsibilities will entail upon them others in which the whole of society is interested. No better illustration of this can be found than a consideration of the necessity for the union of medical men in defence of their conduct when it is assailed, and the student can hardly be told too early in his career that personal insurance against perils of professional life will be a needful protection. In the work of their calling the risk to which doctors may be exposed is frequently exemplified in the lay press, and more particularly in our own columns, and a perusal of the annual reports of the Medical Defence Union and of the London and Counties Medical Protection Society reveals many cases, which have not been made public, where had it not been for the intervention of these societies serious consequences might have resulted for the medical practitioner, as the victim either of ignorance or blackmail. Further, it sometimes happens that a medical man is inequitably dealt with by a public body in whose service he is, and here again the intervention of one of the medical defence societies may save him from injustice, inconvenience, or expense. The past year has afforded striking examples of the dangers to which medical men are subjected in the exercise of their professional duties, the details of which must be fresh in the memory of all. It may be some years before the need will arise for the student of to-day to take advantage of the defence agencies, but the sooner he gets the impression that he will need protection the better.

The necessity to provide for individual defence, however, is but one subject, though an appealing one, of the many that should be brought to the attention of the medical student. All the matters where medicine, which more and more is permeating the general affairs of society, comes into direct contact with local government, and especially with health organisation, are subjects for exposition to those who are in training for our calling. Intensely individual as the practitioner must be in the conduct of his practice as between his patient and himself, in public affairs he has to coördinate his views with those of others who are regarding these affairs in a different way, and his value as a doctor as well as a citizen will be enhanced by his comprehension of the situations in which he will find himself in any intimate dealings with health authorities or the administration of National Insurance. It used to be urged that the medical schools should provide instruction upon the vaguely defined code of mutual good manners called medical ethics. But this medical etiquette was apt to degenerate into a formulary, in which the public interest, though at the bottom of the rules, was not prominently presented to the students. What would be of the greatest value to them is an orderly presentation, especially when their pupillage is drawing to a close, of the position of the doctor in the machinery of society, so that they could appreciate the lines which they must follow when they have to stand up rigidly for the medical view, supporting the attitude in the only proper way—namely, by the arguments proving desire for the public weal.

NAVAL MEDICAL SERVICE.

THE life offered to officers of the Royal Naval Medical Service is one that ought to appeal to a large section of recently qualified medical men. There is no intention in what follows, under this or the subsequent headings, to pit one Service against the other or to recruit in one direction more than in another. The particular regulations for each Service should suffice to give each man the necessary impetus for a decision.

In our notes upon the Service in the Students' Number last year we found it useless to disguise the fact that the attitude of the authorities in respect to the compulsory retirement at the age of 50 of a group of surgeon commanders who were under contract to be employed until the age of 55 had produced an unfortunate impression, and we stated the difficulties created. It is good, therefore, to be able to report that efforts made by the British Medical Association through Sir Richard Luce, M.P., chairman of the Naval and Military Committee, have been successful, and that an increase in the amount paid to senior surgeon commanders on compulsory retirement has been secured. The Admiralty has raised its offer by £50—that is to say, instead of £250, these officers will now be offered £300, on a sliding scale, on their compulsory retirement before the normal expectation under the 1920 regulations. The recompense seems hardly adequate, but as nothing better seems likely to be secured, the Naval and Military Committee of the Association have recommended the acceptance of the offer. Sir Percy Bassett-Smith, the representative of the Service on the Council of the B.M.A., has expressed the view that the relations between the Association and the Admiralty can start again with a clean sheet, the attitude of advising young members of the medical profession to look askance at the chances of a medical career with the Royal Navy being discontinued.

In the Navy the young medical officer sees the world in congenial company and with an assured position, the pay is good, the pensions are commensurate, and the opportunities offered now for scientific work are real, while, if they are taken, promotion awaits the officer on grounds of professional merit.

Rank of Surgeon Lieutenant-Commander will be granted to surgeons at the expiration of six years from date of entry, and the point upon which stress should be laid is that special promotion can be made in cases of conspicuous professional merit, which is thus placed on a par with general service. Six years later the period of promotion to Surgeon Commander is reached, after the qualifying examination has been passed, when again special promotions can be made for conspicuous professional merit as well as for distinguished service; but promotions are limited in number, save, of course, for gallantry in action. This recognition of professional attainment should prove a very real incentive to progressive scientific work. The same principle prevails in the higher ranks. Promotions to Surgeon Captain and later to Surgeon Rear-Admiral are made strictly by selection, but are confined to officers who prove fitted, both professionally and as administrators, for this rank.

Naval life may lead to opportunities for putting into practice much of what has been learned in the clinical wards of a hospital. Further, the opening for preventive medicine is large and many-sided, while appointments to the large shore establishments enable medical officers to keep their work modern.

New chemical explosives, as well as the extraordinary behaviour of common articles under extraordinary conditions of stowage, furnish perpetual problems and surprises for the medical officer on board ship, and bring him into intimate connexion with his charges in a way that is particularly necessary considering the conditions of life. No medical officer can expect to succeed unless he secures the confidence of those committed to his charge, and the health lectures which he is bound to deliver will be much more fruitful if they are delivered to an audience which trusts him. Moreover, the delivery of official lectures does not end this side of the medical officer's duties. He must be ready to answer questions, sometimes of real acuteness, which are put to him by the modern blue-jacket, and he will find that his lectures will often afford a starting point of work that may develop into great professional interest. Thus, without his being necessarily a psychologist, his influence will be felt by both officers and men, until the well-being of the ship may be profoundly affected by the extent of his tact and skill; for example, small matters assume undue proportion under stress of confinement, and the medical officer should be quick to detect danger signs and warn his commanding officer. Numerous changes have been introduced during the last 20 years into the naval dietary, many of which were the outcome of representations and research by naval medical officers. The work wants carrying on, for much of it has gone to show that the food problem is very complicated. Every medical officer on board ship should make himself acquainted with food values and the human powers of assimilation under varying conditions of work and climate, and here there is ample scope for research. The modern requirements of gunnery and navigation necessitate precision in their use and have made ophthalmology a valuable subject for study in the Navy. The physical training of both officers and men is based on physiological axioms which are peculiarly the field of the medical officer; this training should be the subject of a watchful eye. There is no lack of scope here for professional work without making any reference to the vast problems which have to be faced when the medical officer has to arrange his particular department to the best advantage during or after an action. It is certain that he will not be able to do this unless in times of peace he gets himself ready by study. Lastly, there is the whole field of venereal and tropical disease.

The young medical officer need not be afraid that his work will be without scientific interest if he takes the opportunities offered him.

Conditions of Service.

The rates of pay of the Medical Service are subject to periodical revision in the light of the cost of living, and it is necessary to indicate as closely as practicable the extent and methods of the periodical revision.

In order that students may be under no misapprehension regarding their remuneration should they decide to join the Naval Medical Service, it should be clearly understood that when the pay of naval officers was revised in 1919 it was definitely laid down that 20 per cent. of the rates of full pay, unemployed pay, half pay, and retired pay was to be considered as due to the high cost of living in 1919, and that it should be subject to change periodically either upwards or downwards according as the cost of living rose or fell. The first revision took place in July, 1924, when all the rates were reduced by approximately 5½ per cent., and further revisions (not necessarily reductions) are due every three years—i.e., in July, 1927, July, 1930, and so on.

The pay of the Naval Medical Service is shown in two tables, one showing the scale introduced in 1919, which is described as the standard rates and of which 20 per cent. is variable, and the other showing the actual scale in force from July 1st, 1924, to June 30th, 1927.

For the time being the regulations for entry by examination into the permanent service are in abeyance, but a short-service scheme providing for transfer to the permanent service has been inaugurated. The regulations for the entry of surgeon lieutenants under this scheme provide for the usual qualifications of registration, good character, physical fitness, and age—the age not to exceed 30 years. The conditions of service are a three years' engagement with an option of a further year, to serve when and where required under the general rules of the service as regards discipline, and to rank with, but after, surgeon lieutenants in the permanent service, and to receive two calendar months' notice of services being no longer required.

As from July 1st, 1924, the pay is £1 5*s.* (standard rate £1 6*s.* 0*d.*) per day or £456 5*s.* (standard rate £183 12*s.* 6*d.*) per annum, while there is a gratuity, not subject to variation with the cost of living, on discharge of £8 6*s.* 8*d.* for each completed month of service. All officers during service are accommodated and victualled on the usual service scale or receive lodging money and provision allowance in lieu, at rates subject to periodical revision. The present rates of lodging money and provision allowance are £80 and £55 a year respectively. Unlike permanent officers, medical officers entered for short service are not liable to periods of unemployment on unemployed or half pay or eligible for retired pay in respect of service. If, however, such an officer were invalided for a cause certified by the competent naval medical authority as attributable to the conditions of service, he would be eligible for disability retired pay in lieu of the gratuity on discharge referred to above. Similarly, in the event of his death from a cause attributable to the service his widow and children would be treated in the same manner as the widow and children of an officer on the permanent list. There is an equipment allowance for ordinary uniform of £50, but the officer provides himself with a pocket case of instruments and a stethoscope.

A short-service surgeon lieutenant after six months' service, on application to the Secretary of the Admiralty, may be considered for transfer to the permanent service on a satisfactory report being received from the senior medical officer of the Squadron, Hospital or Depôt in which he has served or is serving as to his professional ability, and a favourable report from his commanding officer as to conduct. Such candidates must have been under the age of 28 on joining for short service, and officers so transferred will not be eligible for the gratuities provided. They will be permitted to count their seniority from date of entry for short service for purposes of promotion and for increment of full pay, and similarly they will be permitted to count their service from the date of entry for purposes of retired pay, but for purposes of retiring gratuity on the permanent officers' scale their services will be reckoned only from the date of transfer to the permanent list, this date being that of receipt in the ship or establishment in which the officer is serving of the order for his transfer to the permanent list. Until that date he will retain his temporary rate of pay.

If a short-service lieutenant transfers to the permanent service he will then come under the following conditions of pay and pensions:—

Standard and Present Rates of Pay.

Rank.	Standard rate.						Rate from July 1st, 1924.					
	Year of 365 days.			One day.			Year of 365 days.			One day.		
	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.

Surg. Rear-Admiral . .	1916	5	0	5	5	0	1809	15	10	4	19	2

On first appointment to the service, medical officers will receive full pay from date of appointment, but subject to the provisions of Article 1347 of the King's Regulations.

Officers of the permanent service are eligible during periods of unemployment for unemployed pay and half pay. The rates of unemployed pay and half pay, and the conditions under which they are granted, are the same as in the dental branch and are set forth in detail later in this article.

Flag Allowances.

An allowance of 5*s.* a day in addition to full pay is granted to the Senior Medical Officer of a flagship bearing the flag of a Commander-in-Chief. An allowance of 2*s.* 6*d.* a day is granted to the Senior Medical Officer of a ship bearing other flags or broad pendants.

Standard Rates of Retired Pay.

Compulsory retirement will be as follows:—

(i) Surgeon Rear-Admirals retire at the age of 60 with retired pay at the rate of £900 per annum plus £22 per annum for each year's service over 27 years counting for retired pay, subject to a maximum rate of £1010 per annum. If, however, less than 27 years' service counting towards retired pay is rendered, a deduction of £22 per annum is made for each full year wanting to complete that period, subject to a minimum of £790 per annum.

(ii) Surgeon Captains retire at the age of 55. Maximum retired pay, £900.

(iii) Surgeon Commanders retire at the age of 50. Maximum retired pay, £600.

(iv) Surgeon Lieutenant-Commanders and Lieutenants retire at the age of 45. Maximum retired pay, £450.

Subject to these maxima, the rates of retired pay for Surgeon Captains, Surgeon Commanders, Surgeon Lieutenant-Commanders, and Surgeon Lieutenants are as follows:—

Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)		Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)	
			Addition.	Deduction.				Addition.	Deduction.
	£ (p.a.)		£ (p.a.)	£ (p.a.)		£ (p.a.)		£ (p.a.)	£ (p.a.)
55	790	24	22	15	47	562	20	15	15
54	765	24	22	15	46	525	20	15	15
53	743	23	22	15	45	487	19	15	15
52	720	23	22	15	44	450	19	15	15
51	697	22	22	15	43	412	18	15	15
50	675	22	15	15	42	375	18	15	15
49	637	21	15	15	41	337	17	15	15
48	600	21	15	15	40	300	17	15	15

(p.a.) = per annum.

(A) Addition for each full year's service in excess of that specified in column 3 or deduction for each full year wanting to complete that period of service—addition or deduction limited to five years in each case.

Twenty per cent. of all the rates of retired pay referred to above is variable with the cost of living, and the rates at present in course of payment are approximately 5½ per cent. below those given above.

DENTAL BRANCH.

The Naval Dental Service offers similar opportunities to qualified dental surgeons except that higher rank than that of Surgeon Commander (D) is not open to them. They are provided with suitable surgery accommodation equipped with modern appliances and supplied with all material required for their work, and there is every opportunity for them to maintain a high standard of professional skill.

Entry is by competition, the Competitive Entrance Examination being similar in scope to the Final Qualifying Examination. Candidates are required to produce the usual certificates of birth, registration and of character, and must be physically fit for service anywhere. They must not be more than 28 years of age on the day of commencement of the entrance examination. An outfit allowance of £50 is payable to officers finally entered and commissioned.

Provision has been made for candidates who, at the time of passing the examination, hold or are about to hold an appointment as Dental Officer in a recognised Civil Hospital. The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list. It is also proposed to allow a three months' Post-graduate Course to Surgeon Lieutenant Commanders (D) of over two years' seniority.

As in the case of the medical branch, 20 per cent. of the rates of full pay, unemployed pay, half pay, and retired pay introduced in 1919 is considered as due to the high cost of living in 1919 and subject to change periodically either upwards or downwards according as the cost of living rises or falls. The first revision took place in July, 1924, when all the rates were reduced by approximately 5½ per cent., and further revisions are due every three years—i.e., in July, 1927, July, 1930, and so on. The following table and paragraphs show the standard rates introduced in 1919, of which 20 per cent. is variable and the present rates which will operate from July 1st, 1924, to June 30th, 1927. The rates of full pay are as follows:—

Full Pay.

Rank.	Standard rate.		Rate from *July 1st, 1924.*	
	Year of 365 days.	One day.	Year of 365 days.	One day.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Surg.-Lieut. (D) on entry..	401 10 0	1 2 0	380 4 2	1 0 10
After 3 years	492 15 0	1 7 0	465 7 6	1 5 6
Surg. Lieut.-Comdr. (D) on promotion	593 2 6	1 12 6	559 13 4	1 10 8
After 3 years	629 12 6	1 14 6	596 3 4	1 12 8
„ 6 „	666 2 6	1 16 6	629 12 0	1 14 6
„ 9 „	730 0 0	2 0 0	690 9 2	1 17 10
Surg.-Comdr. (D) on promotion	775 12 6	2 2 6	733 0 10	2 0 2
After 3 years	848 12 6	2 6 6	803 0 0	2 4 0
„ 6 „	921 12 6	2 10 6	869 18 4	2 7 8
„ 9 „	994 12 6	2 14 6	939 17 6	2 11 6

On first appointment to the Service, Dental Officers will receive full pay from the date of appointment, but subject to the provisions of Article 1347 of the King's Regulations, 1913.

Dental Officers are eligible for the same rates of lodging and provision allowances as other officers of equivalent rank and are entitled to the same privileges. The rates of half-pay are:—

Unemployed Pay and Half Pay.—A distinction is to be drawn between—

(*a*) Officers awaiting employment.

(*b*) Those who are permitted for private reasons which the Admiralty regard as satisfactory to refuse an appointment or to have their appointment cancelled or who are unemployed at their own request or in consequence of misconduct.

In the former case—

(*a*) Officers are to receive unemployed pay as follows:—

For the first six calendar months full pay of rank (without allowances).

For the next six calendar months:—

Rank.	Standard rate per diem.	Rate per diem from July 1st, 1924.
	£ s. d.	£ s. d.
Surgeon Lieutenants (D)	0 17 0	0 16 0
Surgeon Lieutenant Commanders (D) ..	1 2 6	1 1 3
Surgeon Commanders (D)	1 7 6	1 6 0

Thereafter:—Half the full pay of their rank and seniority on the Executive Officers' scale, namely:—

Surgeon Lieutenant (D)	0 8 6	0 8 0
„ „ of 4 years' seniority	0 10 0	0 9 5
Surgeon Lieutenant Commander (D).. ..	0 15 0	0 14 2
„ „ of 3 years' seniority	0 16 0	0 15 0
„ „ of 6 years' seniority	0 17 0	0 16 1
Surgeon Commander (D)	1 0 0	0 18 11
„ „ of 3 years' seniority	1 2 0	1 0 9
„ „ 6 „ „	1 4 0	1 2 8
„ „ 9 „ „	1 6 0	1 4 7

Unemployed pay will not, however, be granted in cases where an officer is undertaking continuous professional work for which payment is made.

In the latter case, (*b*), Officers may receive half the full pay of their rank and seniority on the Executive Officers' scale.

Periods during which unemployed Full Pay or Unemployed Pay are received will only count as half-pay time—that is, as one-third of full service.

An Officer who is permitted, for private reasons, to decline an appointment, or to have his appointment cancelled will not be entitled to any Unemployed Pay. In such cases, Officers may be placed on Half-Pay.

The conditions of retirement, Widows' Pensions, Leave, &c., are the same as for medical officers of equivalent rank and seniority.

Arrangements are also made whereby officers may be allowed to withdraw from the Service after four years' service and receive gratuities on the following scale:—

Gratuities will be awarded on retirement and withdrawal on the undermentioned scale.

Rank.	Gratuity.
	£ s. d.
Surgeon Lieutenant (D), Surgeon Lieutenant-Commander (*D*), and Surgeon Commander (D):	
After 4 years' full-pay service	500 0 0
„ 8 „ „ } including service allowed by paragraph 3	1000 0 0
„ 12 „ „ } including service allowed by paragraph 3	1500 0 0
„ 16 „ „ } including service allowed by paragraph 3	2250 0 0

ARMY MEDICAL SERVICE.

Competitive examinations for commissions are held twice a year, usually in January and July. The Regulations for admission to the Royal Army Medical Corps should be obtained from the Army Medical Department, War Office, London, S.W. 1, and carefully studied.

The recent alterations in the conditions of service in the Royal Army Medical Corps, which constituted, as we said at the time, the greatest reform that has taken place in that Service for a generation, have fulfilled much of their promise. For many reasons which are obvious and have been detailed on previous occasions, the Service can be recommended to young medical practitioners. But there are things which the man who contemplates joining the Service should bear in mind.

The rates of pay and allowance are good; the chances of seeing the world and the opportunities for post-graduate study are generous, and the work is nowadays varied, responsible, and interesting. At certain periods the officer is relieved from all other duties for five months for the purpose of post-graduate study. During this period he is on full pay and the fees for his courses of instruction are paid by the State. His time is devoted to post-graduate work, and the leading clinical and scientific institutions are coöperating to secure that this post-graduate work shall be real and fruitful. Officers who show a marked aptitude for special subjects and have had previous practical experience in them are now selected to undergo a specialist course lasting for a further four months, thus giving these officers a post-graduate course of nine months. At the same time, in districts where the privilege would be of the most practical value, opportunities are forthcoming for young officers to attend the clinical practice of large local general hospitals.

By a Royal Warrant issued in September, 1919, medical and combatant officers were placed on the same footing as regards retired pay, and the fact that medical officers enter the Service after a long and expensive training some five years later in life than combatant officers was overlooked. This inequality of treatment has since been rectified, with the result that a medical officer of 20 years' service gets approximately £70 per annum more pension than a combatant officer with the same number of years' service.

ROYAL ARMY MEDICAL CORPS: PAY AND ALLOWANCES.

Rank.	Pay per diem.*	Rations†	Servant. †	Married.			Unmarried.		Approximate yearly total.

Major-General	4 0 10	1 8	4 0	11 0	5 7	2 0	11 0	4 0	2082	2017

* Pay Warrant rates less 5½ per cent. from July 1st, 1924, vide A.O. 93 and 201 of 1924. The Pay Warrant rates when granted were made subject to revision to an extent not exceeding 20 per cent., according to variation in the cost of living. The next revision takes place from July 1st, 1927.

† Rates of allowances vary from time to time and issues are subject to conditions laid down in the Allowance Regulations.

Dissatisfaction, however, has been expressed on the subject of pensions under the 1919 Warrant for majors retiring after 20 years' service. The matter was brought up at the recent annual meeting of the British Medical Association in Bath, when, on the motion of Sir Richard Luce, speaking on behalf of the Naval and Military Committee, a resolution was carried indicating the strong disapproval on the part of the Association of the treatment of these officers. Sir Richard Luce explained that the pre-war retired pay of a major after 20 years' service was £1 a day, and following the 1919 Warrant the amount was increased to £300 a year, but that reductions made in accordance with the cost of living might bring the pension to less than £1 per diem—that is to say, a smaller sum than was provided by the Warrant under which the officer joined. An additional grievance was that, irrespective of subsequent possible deductions, the increase granted to majors under the 1919 Warrant was proportionately less than most of the pension increases to other ranks. The Secretary of State for War in an interview with the Committee made an offer which might have proved acceptable, but this offer has subsequently been opposed by the Treasury.

The Directorates in Pathology and Hygiene have proved a marked success. The scheme permits specially selected men to rise from all ranks to Major-General on the strength of their scientific work, whereas formerly, whatever a man's qualifications or abilities, on attaining the rank of Lieutenant-Colonel, he went off into administrative work, leaving his scientific duties to his juniors. If he preferred to remain working in bacteriology, in preventive medicine and hygiene, or in tropical diseases, it is true he could do so, but, except in extraordinarily fortunate circumstances for himself, he would find that his devotion to science had cost him all chances of further rise in his Service, promotion being reserved for the administrative billets. This now has all been changed, and the change has its expression in these Directorates. All ranks up to and including the rank of Lieutenant-Colonel can draw specialist pay and hold appointments carrying charge pay. The following is the scale of additional pay and charge pay:—

Additional Pay and Charge Pay for Officers of the R.A.M.C.

(1) Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by Our Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under, within a limit of 5s. a day:—

Operative Surgery, advanced; Medicine; Ophthalmology; Gynæcology and Midwifery; Dermatology, including Venereal Disease, 5s. daily.

Otology, Laryngology, and Rhinology; Radiology; Anæsthetics; Mental Diseases; Hygiene; Pathology; subjects other than above, at the discretion of Our Army Council, 2s. 6d. daily.

Officers granted temporary higher rank while holding appointments in the services of hygiene and pathology will not be eligible for additional pay as specialists while holding such temporary rank.

(2) (a) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds ..	2s. 6d. daily.	300 beds ..	7s. 6d. daily.
150 ,, ..	5s. 0d. ,,	500 ,, ..	10s. 0d. ,,

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates.

	Daily. s. d.
(b) Senior medical officer, Royal Arsenal not exceeding	10 0
(c) Officer in command of the depôt, Royal Army Medical Corps	5 0
(d) The senior officer of Our Army Medical Service with an army in the field: A rate to be fixed by Our Army Council according to the magnitude of the charge.	
(e) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5 0
(f) Adjutant R.A.M.C. Depôt	5 0
(g) Adjutant R.A.M.C. (Territorial Army)	2 6

Further, an officer, graded as a specialist, and appointed to the charge of a medical or surgical division of a general hospital may be allowed to retain his additional pay and to draw the rate of charge pay laid down for the officer in charge of a medical or surgical division of a general hospital, provided that the total of additional and charge pay so drawn does not exceed the rate of charge pay drawn by the officer in charge of the hospital. With this exception charge pay and additional pay as specialist will not be issuable concurrently. It may be here pointed out that the distinction between scientific and administrative work is largely verbal. Take the conduct of a large hospital—is it possible to separate the scientific routine which is designed to ensure progressive therapeutics from the administrative work which provides and maintains the premises and service, and selects and oversees the personnel?

Under the conditions enumerated the possibilities for good workers is very great in the R.A.M.C.; they will attain to positions of proper trust and emolument by scientific work. This should much improve recruiting among the officers of the R.A.M.C. But there will almost certainly follow arrangements by which all special medical service will receive higher consideration in the Corps. Not only is there in the work of the Army Medical Department scope for original labour and research in tropical disease, in preventive medicine, and in bacteriology, as well as in the vast clinical field open to the specialist in medicine, surgery, or gynæcology, in venereal disease, in ophthalmology, and so on, but it is proposed to develop a scheme whereby child welfare shall be undertaken systematically by the R.A.M.C. A scheme of this sort is already running successfully at Aldershot, and we see in this direction a fine opening for preventive medicine, and one which should bring the officers of the R.A.M.C. into touch with the soldiers in a valuable and intimate manner.

The above schemes for the stimulation of purely professional work among officers of the Corps must not be taken to imply that instruction in administrative work has been overlooked. One of the lessons of the war was that good administration must exist for the fullest benefit to be obtained from the professional talent available. The necessity of training officers who may display capacity for organisation and administration has not been lost sight of, and there are many appointments of varying degrees of importance and responsibility open to officers who desire to take up this side of the Corps' duties.

Retirement and Retired Pay.

The following are the rates of pension and retired pay:—

1. Retired pay will consist of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible for retired pay.

2. The scale will be as follows, subject to the reduction of 5½ per cent. referred to below:—

(*a*) Service element.—£15 a year for each completed year of service as a medical officer.

(*b*) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
Major	12	12	120
Lieutenant - Colonel	150	30	240
Colonel	290	50	390
Major-General ..	440	50	540
Lieutenant - General	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together:—

	£		£
Captain and Subaltern ..	300	Colonel	800
Major	450	Major-General ..	1000
Lieutenant-Colonel ..	600	Lieutenant-General	1200

The above rates are those laid down in the Pay Warrant. They have been reduced by 5½ per cent. as from July 1st, 1924. (See footnote,* p. 463, and A.O. 205/24.)

3. Officers with 8½ and less than 20 years' service as medical officers may be permitted to retire with a gratuity varying from £1000 to £2500.

Arrangements have been made for the appointment of Consultants in both Medicine and Surgery and the ranks of Colonel and Major-General will now be open to such Officers. The duties of these Officers are to visit all Commands and advise the Director-General, as the result of their inspections on the spot, with regard to the professional work being carried on in the hospitals, and the degree of efficiency attained by the personnel with whom they are respectively concerned. This should ensure a high standard of performance if only because of the satisfactory feeling that good work will not by accident remain unnoticed.

The present holders of these posts are Consultant in Surgery, Colonel J. W. West, late Professor of Surgery at the Royal Army Medical College; Consultant in Medicine, Colonel J. C. Kennedy, late Professor of Tropical Medicine at the Royal Army Medical College.

THE ARMY DENTAL CORPS.

The Corps is administered by the Director-General, Army Medical Services. It is a joint service for the Army and Royal Air Force and personnel is required to serve under either force and be interchangeable. Officers and other ranks posted for duty with the Royal Air Force will perform their duties under the Regulations of the Royal Air Force for the employment of dental personnel, but the conditions in the following tables apply equally in either force. Promotion is carried out on one general list. The regulations for admission to the Army Dental Corps should be obtained from the Secretary, War Office, and carefully studied.

OFFICERS: *Appointment and Promotion.*

1. Commissions as lieutenants in the Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council.

2. An officer shall be eligible for promotion to the rank of captain on completion of three and a half years' service in the Corps provided he has previously qualified in such manner as may be prescribed by the Army Council.

3. Promotion to the rank of major and lieutenant-colonel to fill the establishments laid down from time to time for those ranks, shall be made by selection of the Army Council, provided the officer has previously qualified for promotion to those ranks in such manner as may be prescribed by the Army Council.

4. Certain appointments in the rank of lieutenant-colonel and major have been approved to fill the establishment. The remainder of the appointments are in the rank of lieutenant, except in cases where service of three and a half years or more has been given as a temporary dental officer when the rank of captain will be given. Service as a temporary dental officer will count towards the three and a half years for promotion to captain.

Pay.

The following are the rates for officers of the Army Dental Corps:—

	Per diem. £	s.	d.
Lieutenant	0	18	10
Captain	1	3	8
Captain { after 6 years' total service ..	1	5	0
„ 10 „ „ „	1	7	0
Major	1	11	3
Major, after 15 years' total service	1	15	10
Lieut.-Colonel	2	4	10
Lieut.-Colonel { after 20 years' total service ..	2	7	4
„ 25 „ „ „ ..	2	9	8

These rates are 5½ per cent. below those shown in the Pay Warrant, 1922. The latter, when granted, were made subject to revision to an extent not exceeding 20 per cent., according to variation in the cost of living. The next revision takes place on July 1st, 1927.

Allowances.

The allowances for officers of the Army Dental Corps are at the same rates as for officers of the R.A.M.C.

Retirement and Retired Pay or Gratuity.

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after twenty years' service.

(3) Earlier retirement on gratuity may be allowed:—

After 8½ years' service in the Corps, gratuity of £1000.
„ 15 „ „ „ £1800.
„ 18 „ „ „ £2500.

(4) Retirement will be compulsory at the age of 55 years.

(5) A lieutenant who does not qualify for promotion within three and a half years' service in the Corps will be retired; and a captain who fails to qualify for promotion to major within twelve years' service in the Corps will be retired on any gratuity for which he may be eligible under paragraph 3.

Other Ranks.

The rates of pay of warrant officers, non-commissioned officers and men are those provided in the Warrant of Sept. 13th, 1919, *vide* A.O. 325/19.

The aim of the Corps is the prevention of wastage of man power on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier will be re-inspected at least once a year and his dental efficiency maintained at the best standard possible. As recruits are not now enlisted unless they have sufficient natural teeth to enable them to masticate efficiently it is hoped that the conservative nature of the treatment they will receive will reduce considerably the percentage of artificial dentures required.

The "other ranks" of the Corps consist of dental mechanics and clerk orderlies. Training of dental mechanics has been proceeding for some time at the Central Dental Laboratory, Aldershot, and it is not proposed to open recruiting at present for this section. A limited number of clerk-orderlies is now being enlisted, and these men receive their training at the Royal Army Medical Corps Depôt.

INDIAN MEDICAL SERVICE.

WE cannot yet foretell how and to what extent the Indian Medical Service will be affected by the report of the Royal Commission on the Superior Civil Services in India. The report is the outcome of the Indian reform scheme, the essence of which is an increasing participation by Indians in the government of the country, and as far as the Indian Medical Service is concerned, the recommendations of the Commission can be summarised with fair accuracy.

Contrary to the recommendation of the Verney-Lovett Committee, the Commission has recognised that the medical needs of both the British and Indian armies in India should be provided for in future by the Royal Army Medical Corps (India) which should absorb the Indian Medical Service, no attempt being made to perpetuate that service as at present constituted. This recommendation is in accordance with the scheme elaborated by Sir Charles Burtchaell in 1919, and printed at length as an appendix to the Commission's report. At the same time, a new civil medical service is to be constituted in each province recruited by competitive examinations held both in England and India. To meet the medical needs of British officers in the Civil Service and their families a minimum number of British officers is to be maintained in this civil medical service, the limit to be prescribed for each province by the Secretary of State, on whom in the last resort is to rest the responsibility for their maintenance. Of this British element, one half, or the number required for the military reserve (whichever is the larger), is to be ear-marked for British officers seconded from the R.A.M.C., the remainder being those succeeding in competitive examination. It is further recommended that, subject to the existing rights of present members of the Indian Medical Service, all scientific chairs in Government colleges and hospitals shall be thrown open to all candidates, the clinical chairs alone being reserved for members of the civil medical services so far as suitable candidates are available.

Whatever the ultimate arrangements may be, the necessity will remain to provide a European medical service in India so long as Europeans are employed in the various departments of the Civil Service.

It would be idle to pretend that the I.M.S. is in a happy plight at the present time. The announcement of terms for special recruitment which was published in THE LANCET of March 14th this year showed not only that the future is unsettled, but also, by implication at any rate, that the ordinary methods of replenishing the cadre by the medium of competitive examination have failed. Complete grounds on which to form a definite estimate of the attractions of the service are lacking, but even in the present state of flux we must consider here the past and present conditions, and try to come to some such provisional conclusion with regard to the future as may help to guide possible candidates in deciding whether to apply or not when vacancies are again advertised.

There is, of course, a general feeling of malaise and uncertainty, not only in the I.M.S., but in other Indian services, though there are causes of dissatisfaction special to the I.M.S. Together with the I.C.S., the police, and other departments, the officers of the I.M.S. suffer from increased cost of living, the diminution of social amenities in the smaller stations which are rapidly becoming Indianised, and restricted opportunities for sport. There is also, in many cases, a feeling of not being wanted, and in some districts the attitude, even of the rural population, is neither so helpful nor so friendly as it was. With the contraction of the cadre consequent on the reduction in the number of the posts reserved for the I.M.S., more time will necessarily elapse before men can hope to get into civil employ. Then, with the increase of Indian private practitioners, some of whom have obtained the highest British qualifications, opportunities for private work are diminishing, while there will be with many a reluctance to serve under Indian superiors.

It has thus to be admitted that in many ways the conditions of service have considerably deteriorated, but there is another side to the picture, and the changes are by no means all on the debit side. While various general considerations affect the service—like the other services, the work is of a highly technical nature, so that the executive cannot be much subject to interference, whether from European or Indian superiors, and the social effect of Indianisation will be less, for the reason that European I.M.S. officers will no doubt be mostly utilised for stations with considerable European communities. Thus adverse popular sentiment should affect the I.M.S. but slightly, and there will be little change in the work, while the alterations should be largely for the better with the progressive improvements in the equipment and organisation of hospitals. There are not so many efficient surgeons in the provinces that good men, whether European or Indian, will not make their presence felt and appreciated, and the fewer Europeans of the right type that are available the more useful their work will be individually to the country, and the more profitable to themselves. The opportunities for professional work have always been the main inducement to ambitious British medical men to take up appointments in India, and those opportunities remain as attractive as ever, except in the teaching institutions, where the indications unfortunately are that fewer posts will in future be available for officers of the I.M.S., either European or Indian.

Against the undue delay in getting civil employ, again, has to be balanced the fact that when civil posts are obtained they will be better than any man could ordinarily have expected under the former conditions, immediately after entry into the civil department. Many of the smaller and less desirable stations will have disappeared from the I.M.S. list, and in general those which remain will be not only more desirable but more remunerative. It has to be admitted, though, that the time for the accumulation of large fortunes in private practice has for the most part passed.

As regards emoluments, no doubt expenses have increased, but some years ago an all-round increment of about 50 per cent. was granted, and the concessions under the recommendations of the Lee Commission will be by no means negligible. They include, amongst other things, a reasonable number of free passages for both the officer and, if married, his family, and a considerable addition to cash receipts in the form of facilities for remission home at a specially favourable rate of exchange.

Especially with regard to the military appointments there is much to be put to the credit side in the changes which have occurred of recent years. The station hospital system, for instance, has not only rendered the position of the medical officer much more independent, but it has made team work possible, increased the opportunities for professional activity in every direction, enabling men to specialise in various departments of medicine and surgery. In both military and civil departments, again, improved travelling regulations, introduced a few years ago, have removed one very great hardship. For under the old rules transfers nearly always implied a serious loss; nowadays they are carried out under much more reasonable conditions.

It will be seen from the regulations for special recruitment, and other indications, that the future of the I.M.S. is still hanging in the balance. In any case, however, the interests of suitable men joining at the present time would presumably be properly safeguarded, and reasonable security of tenure granted. with some short-term gratuity system (such as that recently offered) and proportionate pensions to fall back upon in case of need and after a certain time of service. It appears that even in the present circumstances the service offers considerable attractions.

AIR FORCE MEDICAL SERVICE.

The Royal Air Force Medical Service offers a career for medical men which should prove both attractive and interesting. The rates of pay and allowances are good, and a new field of scientific interest is opened up by the manifold problems which the circumstances of aviation produce. The physical and mental fitness for, and reaction to, the varied conditions under which the flying personnel perform their functions provide much scope for research. As promotion to the higher ranks of the Service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely scientific, as opposed to administrative, appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop a talent for administration.

The establishment will consist partly of permanent and partly of short-service officers. An officer will on first entry be granted a short-service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council on the recommendation of the Director of Medical Services), and of four years in the Reserve of Air Force officers. Selections for permanent commissions will be made from officers holding short-service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list.

Short-service officers who are approved for permanent commissions, but for whom there are not vacancies in the Royal Air Force Medical Service, may, under certain conditions, be considered for transfer to the Royal Army Medical Corps, counting their time served in the Royal Air Force towards increments of pay and retired pay in the Royal Army Medical Corps.

Officers who have been selected for permanent commissions may be permitted to attend for a period not exceeding nine months a post-graduate course in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such permission may be granted during the first six years of permanent service, and when attending these courses officers will receive full pay and allowances.

New entrants for the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after 10 years' total service. Accelerated promotion may be carried out, in a limited number of cases, of officers who show exceptional ability after the completion of eight years' service. Promotion within establishment to the rank of Wing Commander will be by selection at any period after 16 years' total service, and to that of Group Captain by selection at any period after 22 years' service.

There will be no competitive examination on entry; candidates must be under 28 years of age, British subjects, the sons of British subjects, and of pure European descent, be nominated by the Dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce—

1. Birth certificate.
2. Medical registration certificate.
3. A declaration containing the following information:—

(a) Age and place of birth.

(b) That he is a British subject and the son of British subjects, and of pure European descent.

(c) That he is ready to engage for general service at home or abroad as required.

(d) The qualifications he is possessed of, and what medical or other appointments he has held (if any).

(e) That he is willing to fly whenever called upon to do so.

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may intrefere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

An officer granted a short-service commission who, at the time of application for such commission held or was about to hold a resident appointment in a recognised civil hospital, may be seconded for the period not exceeding one year from the date of the commission during which he shall hold such appointment. Whilst seconded he will not receive pay from Air Ministry funds, but the period of secondment will otherwise count as service in the Royal Air Force, provided that he will be required to serve for a minimum period of three years on the active list from the date on which he ceases to be so seconded.

Uniform and Equipment.

Medical officers will be required to provide themselves with the uniform of their rank and with the distinguishing badge of the Royal Air Force Medical Service. They will be required to provide themselves with service dress and mess dress. The provision of full dress is entirely optional at present.

An allowance towards the cost of uniform will be made when the officer has been gazetted, as follows:—

(a) If he has had no previous service as an officer in H.M. Forces or if any such previous service was terminated more than three years before the date of joining for duty, £50.

(b) If he is commissioned within three years of the termination of any previous service as an officer in the Royal Navy, Army, Indian Army, or Royal Marines or any of the auxiliaries of those forces, but not in the Royal Air Force or its auxiliaries, £25.

(c) If he is seconded from the Royal Navy, Army, Indian Army, or Royal Marines, £25.

The rates of pay and allowances at present in force are as shown in Table I.

The standard scale of retired pay for Group Captains and lower ranks is given in Table II.

Table II.

Age on retirement.	Standard yearly rate of retired pay.	Years of service.	Addition for each extra year of service.*	Deduction for each deficient year of service.*
	£		£	£
40	300	17	15	15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15
44	450	19	15	15
45	487	19	15	15
46	525	20	15	15

2. The above rates of pay are liable to revision. The standard rates were drawn up in 1919 in the light of the then high cost of living, and 20 per cent. of each of the standard rates is regarded as detachable and subject to alteration, either upwards or downwards as the cost of living rises or falls. The first revision took effect from July 1st, 1924, when a reduction of approximately 5½ per cent. was made in the standard rates. Subsequent revisions will be made at intervals of three years.

3. It must, however, be clearly understood that while every consideration will be given to the reasonable and legitimate interests of individuals, it will be competent for the Air Council at any time to modify the regulations under which the emoluments of the R.A.F. are drawn, and no Officer will be entitled to claim any pay, gratuity, or other advantage conferred by a provision being at any time added to, varied, or cancelled.

4. For the purpose of the issue of allowances a "married officer" is one who is married and has attained the age of 30 or the substantive rank of Squadron Leader or who, irrespective of age and rank, was married on or before Sept. 15th, 1919, and was serving in the Royal Air Force on June 8th, 1922.

5. As allowances are given for specific purposes, the cost of which may vary at comparatively short intervals, the rates of allowances are liable to be reviewed as circumstances may require.

6. A colonial allowance is granted in certain commands abroad in aid of the expenses of living in the countries where the cost is higher than in the United Kingdom.

7. For periods of service given under Indian administration and payment, officers will come under the rates and conditions authorised from time to time by the Indian Government in so far as those rates and conditions may differ from those in this scheme. The Indian rates are at present under review.

There will be a minimum qualifying period for retired pay of 20 years.

The rates of retired pay given above (including the maximum rates) are standard rates which will be subject to revision as stated in paragraph 2 under Table I. The revision will apply to all retired pay which is being drawn at the date of revision as well as to subsequent awards.

Gratuities.

Short-service officers will be eligible for gratuities on passing to the Reserve on the scale of £100 for each of the first two complete years of service, and £150 for each of the third, fourth and fifth complete years. These gratuities will not be payable to officers granted permanent commissions, but the period of service under the short-service commission will count for retired pay.

Medical officers holding permanent commissions may, at the discretion of the Air Council, be allowed to retire voluntarily from the Service after ten years' commissioned service with a gratuity of £1250 or after 16 years with a gratuity of £2000 in lieu of retired pay.

COLONIAL MEDICAL SERVICE.

IN the self-governing dominions, Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland, and territories under their control, such as Papua and the Cook Islands, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; appointments in Egypt and the Soudan are regulated from the Foreign Office; in Southern Rhodesia the appointments are made by the local Government, but the British South Africa Company, London Wall Buildings, E.C., act as their agents in this country; in North Borneo application should be made to the British North Borneo Company, 37, Threadneedle-street, E.C., for appointments; and those in Sarawak are in the hands of H.H. the Rajah. Much valuable information will be found in the "Professional Handbook," Part II., issued by the Oversea Settlement Office, 3 and 4, Clement's Inn, Strand, London, W.C. 2, price 9*d.*

As a general rule, each Colony or Protectorate has its own public service distinct from that of every other; and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another. There are three exceptions to this rule: (*a*) The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, is one service. (*b*) The East African Medical Service, which serves Kenya, Uganda, Zanzibar, Nyasaland, Somaliland, and the Tanganyika Territory is one service. (*c*) In practice the medical services of the Straits Settlements and the Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States or vice versa.

The Colonies, Protectorates, and Mandated Territories to which medical officers are appointed by the Secretary of State for the Colonies are (*a*) the West African—viz., Nigeria, the Gold Coast, Sierra Leone, and the Gambia; (*b*) the East African—viz., the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, the Tanganyika Territory, and Northern Rhodesia; (*c*) the Eastern—viz., Ceylon, the Straits Settlements and Malay States, Hong Kong, Mauritius, and Seychelles; (*d*) the West Indian—viz., British Guiana, Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, British Honduras, and the Bahamas; (*e*) Fiji and the Western Pacific, Cyprus, Gibraltar, St. Helena, Bermuda, and the Falkland Islands; and (*f*) Palestine.

In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. Appointments in Malta are all filled locally. Vacancies occur most regularly and frequently in the West African Medical Staff, the East African Medical Service, and the Straits Settlements and Malay States.

All applicants for medical appointments in the gift of the Secretary of State for the Colonies should be between the ages of 23 and 35,[1] and must be doubly qualified; preference will be given to those who have held hospital appointments as house physicians and house surgeons; testimonials to character and professional competence will be required, and every officer before being definitely appointed will be medically examined by one of the consulting physicians of the Colonial Office: Sir William Prout, C.M.G., O.B.E., and Dr. A. E. Horn, C.M.G., 79, Harley-street, London, W. 1; Sir J. Hawtrey Benson, 57, Fitzwilliam-square, Dublin; Dr. Foster Coates, 9, Shaftesbury-square, Belfast; Lieut.-Colonel Glen Liston, C.I.E., I.M.S., 33, Comely Bank, Edinburgh; and Dr. R. H. Kennan, 2, St. James's-road, Liverpool. Applications for such appointments must be addressed to the Private Secretary (Appointments), Colonial Office, Downing-street, S.W. 1.

EAST AFRICAN MEDICAL SERVICE.

The Medical staffs of the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, and the Tanganyika Territory form one service, the members of which are liable to be posted to any of the Dependencies as the exigencies of the service may require. The preferences of individual officers are, however, taken into consideration as far as possible.

Selected candidates are appointed as medical officers on probation in the first instance for two years, at the end of which period their appointments are made permanent if their service has been satisfactory. Unless the Secretary of State directs to the contrary, they are required to attend a course of instruction at the London or Liverpool School of Tropical Medicine before taking up their appointments. If such a course is not taken before proceeding to East Africa, they are required to take it during their first leave of absence. Medical officers (but not sanitation officers) are permitted to take private practice at some stations, on the understanding that they give precedence to their official duties. It must be understood that additions to their income from this source are not likely to be substantial.

The currency in different Dependencies in East Africa varies. In Kenya, Uganda, and the Tanganyika Territory, an East African shilling (one-twentieth of a pound sterling) is the standard coin. Salaries and sterling allowances are issued locally in respect of resident service at a fixed rate of 20 shillings to the pound sterling. A special local allowance, averaging 15 per cent. of sterling salaries and allowances is at present issued in respect of resident service. The question of the continuance or otherwise of the allowance will be subject to review on Dec. 31st, 1925. In Zanzibar and Somaliland the Indian rupee is the standard coin, and for the present sterling salaries and allowances are issued at a fixed rate of 15 rupees to the pound. No local allowance is paid. In Nyasaland sterling currency is used, and no local allowance is paid.

Officers are provided with quarters free of rent (but not of rates or other similar outgoings), if quarters are available; if quarters are not available, the Government may provide temporary accommodation or alternatively, at the discretion of the Government, an allowance in lieu of quarters calculated at 15 per cent. of the initial salary of an officer's appointment may be paid. The salary of a medical or sanitation officer is £600 per annum, rising by annual increments of £25 to £900 per annum, with efficiency bars at £700 and £800. Officers who possess the Diploma in Public Health on entering the service, or who acquire it while in the service, receive two special increments in the scale.

---

[1] In the case of East Africa, preference will be given to candidates who are over 25 years of age. In the case of Fiji and the Western Pacific, preference will be given to candidates who are under 30.

Officers of the East African Medical Service are permitted to retire with gratuity, if they wish, instead of waiting to retire on pension as follows: (*a*) After nine years' service, of which at least six must have been spent in East Africa, £1000; (*b*) after 12 years' service, of which at least eight must have been spent in East Africa, £1250. If an officer elects to retire with gratuity, he thereby foregoes all claim to pension.

The grades and salaries (apart from ordinary medical and sanitation officers) in the medical departments are as follows:—

Kenya.—Director of Medical and Sanitary Services, £1200; Deputy Director of Medical Service, £1000; Deputy Director of Sanitary Service, £1000; Surgical Specialist, £900 by £50 to £1000; Director of Laboratory, £900 by £50 to £1000; Senior Medical Officers and Senior Sanitation Officers, £800 by £25 to £900.

Uganda.—As Kenya. (There are two Deputy Directors of Medical Service, one being for native services.)

Tanganyika Territory.—As Kenya, except that there is no surgical specialist.

Nyasaland.—Director of Medical and Sanitary Services, £1000; Senior Medical Officer and Senior Sanitation Officer, £800 by £25 to £900.

Zanzibar.—As Nyasaland. There is also a Surgical Specialist at £800 by £25 to £900.

Somaliland.—Principal Medical Officer, £800 by £25 to £900.

Sanitation officers are selected from the ranks of medical officers as occasion arises.

ASIA.

Straits Settlements and Federated Malay States.—European medical officers are appointed on the following scale of salaries: $440 per mensem, rising to $480 per mensem during three years' probation; then, if they are placed on the pensionable establishment, rising to $500 per mensem, and thence by annual increments of $25 per mensem to $800 per mensem, with a strict efficiency bar at $600 per mensem. This scale of salaries has been fixed on the supposition that medical officers join the service at about the age of 27. Above the concluding figure of $800 per mensem there are certain higher appointments as follows: Principal Civil Medical Officer, Straits Settlements, and Principal Medical Officer, Federated Malay States, $1200 per mensem. Class A: seven posts at $1050 per mensem. Class B: nine posts at $850, rising by $30 to $1000 per mensem.

The following temporary allowances are at present paid to all officers recruited from Europe in the Government Services of the Straits Settlements and Federated Malay States: unmarried officers, 10 per cent. of salary; married officers, 20 per cent. of salary. Private practice by Government medical officers is not allowed. They may, however, do, and receive fees for, consultative work, under conditions approved by the Government. Information about general conditions in Malaya is obtainable from the Malay States Information Agency, 88, Cannon-street, E.C. 4.

Seychelles.—The chief medical officer receives Rs.7000 and Rs.300 in fees. There are two assistant Government medical officers, one receiving Rs.6500, the other Rs.6000. One assistant medical officer is provided with free quarters in the New Hospital.

Hong-Kong.—The present establishment of the medical department is: principal civil medical officer, £1000–£50–£1200; eight medical officers, £600–£25–£1000; three port health officers, £600–£25–£1000; bacteriologist, £700–£25–£1000; two health officers, £600–£25–£1000, are also attached to the Sanitary Department. A temporary allowance on a scale varying with the sterling exchange value of the dollar is at present payable. Salaries are converted locally at the rate of 2*s.* = $1. Free quarters are not provided, but in certain instances a rent allowance is paid by the Government.

AMERICA.

British Guiana.—There are the following posts in the medical service of the Colony: one surgeon-general, £1000–£1200 per annum, with consulting practice; one bacteriologist and pathologist, £450–£700 (increment £25), with £50 allowance in lieu of fees; 31 medical officers at £500–£25–£700. Some of the senior posts also carry duty allowances (varying from £50 to £300 per annum) and quarters. All the junior appointments in which private practice is not allowed carry duty allowances. Private practice is allowed in certain cases.

Trinidad and Tobago.—In Trinidad and Tobago there are over 40 appointments. On appointment Government medical officers, who are provided with free unfurnished quarters, receive salary at the rate of £400 per annum with annual increments of £25 accruing from the date of first appointment as supernumerary medical officers, until reaching the maximum of £600. An officer appointed to a district receives, in addition to his salary, a travelling allowance varying from £100 per annum in a normal district to £150 per annum, and is allowed private practice, the value of which is estimated at from £50 to £800 per annum. Officers employed in institution work receive allowances in lieu of private practice varying from £50 (and furnished quarters) to £300. Medical officers having completed 10 years' resident service are pensionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent). There are over 25 appointments. The chief medical and health officer, Grenada, receives £600–£700. The chief medical officer, St. Lucia, receives £600–£700 plus forage and subsistence allowances; the post is pensionable, but private practice is not allowed except as a consultant. Most of the remaining appointments are district appointments with the right to private practice attached; the salaries paid by Government vary from £400–£500, and with allowances in certain cases. The Governor has the power to transfer a medical officer from one island to another at his discretion. The appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The appointments are of the same nature as in the Windward Islands and are pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary varying from £312 to £400, according to station, and the Governor decides as to the district which is to be allotted to him. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands, and in certain districts may be required to perform magisterial duties. The medical officers receive fees for successful vaccinations, post-mortem examinations, attendance and giving evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also as a rule, allowed private practice. The chief medical officer, St. Kitts, receives £700–£25–£750 without private practice.

British Honduras.—There are seven medical appointments (besides the principal post of colonial surgeon) of which six are at a salary of $2430 per annum and one at $3150. Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution. The value of the dollar is approximately the same as that of the United States dollar.

OTHER OVERSEAS APPOINTMENTS.

Fiji and the Western Pacific.—In Fiji the Government medical officers receive a salary of £400, rising by annual increments of £25 to £600, with partly furnished quarters, or a house allowance of £50. In some districts a medical officer is also a district commissioner, with an additional allowance of £150.

They are allowed private practice, on the understanding that their official duties are not neglected. Private practice, however, cannot be guaranteed, and in most districts it is very small in amount. Where no private practice exists, a duty allowance of £50 is granted. They are required either to take charge of hospitals or of districts, at the discretion of the authorities. The posts are pensionable.

In addition to a chief medical officer (£800 a year, rising to £1000), a medical officer of health, Suva (£750–£900, not subject to bonus addition), a medical superintendent, Colonial Hospital (£500–£750, inclusive of allowance as officer in charge of the Medical School), and a medical superintendent, Makogai Leper Asylum (£600 rising to £800), there are in Fiji 11 medical officers, five of whom are also district commissioners. The salaries in Fiji are subject to temporary increases, the rate of bonus at the present time being 15 per cent. of the salary with the addition of £22 10*s*.

The staff in the British Solomon Islands Protectorate consists of one senior medical officer (£650 rising to £750) and two medical officers (£550 rising to £650). A local allowance at the rate of £50 per annum is also paid in respect of actual resident service in the Protectorate. In the Gilbert and Ellice Islands Colony there is one medical officer in charge (£650 rising to £750). Officers may be transferred from Fiji to the Western Pacific and vice versa at the discretion of the Secretary of State.

Cyprus.—There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £900, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer, who is allowed consulting practice only) and receiving 2*s*. per diem forage allowance. There is also a medical officer of health on £600, rising by £20 increments to £720 without private practice; these are the only medical appointments in the island which are open to English candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £750, and private practice. There are also two assistant surgeons with a salary of £720 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The colonial surgeon at present receives £550 per annum, £20 fees as health officer, and £30 horse allowance. Private practice is allowed. The assistant colonial surgeon at present receives £500 a year and a horse allowance, and is allowed a share of the private practice. For contracts and appointments the colonial surgeon also receives about £250 a year and the assistant colonial surgeon about £150.

Falkland Islands.—There are two appointments. The colonial surgeon is paid at the rate of £600 per annum, with free furnished quarters. The assistant colonial surgeon is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters. Private practice is shared between the colonial surgeon and the assistant colonial surgeon. The office of colonial surgeon is pensionable.

Palestine.[2]—The grades and salaries of superior appointments in the Department of Health are: Director, £E1100–50–1400, plus £E100 expatriation allowance. Deputy director, senior medical officer (laboratory section), and senior medical officer (Jerusalem-Jaffa district) £E800–50–1100 plus £E100 expatriation allowance. Chemical analyst, three senior medical officers, and medical officer (Jerusalem-Jaffa district) £E550–25–750 plus £E50 expatriation allowance. The remainder of the staff is recruited locally. The salaries of the two highest grades will be reduced as vacancies occur.

LEAVE AND PENSIONS.

Leave and Passages.—Leave of absence in East Africa on full salary is granted in the normal case after a tour of residential service (of not less than 20 and not usually more than 30 months) to an amount of six days for each completed month of residence (or three days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro, for which full pay is also given. Officers serving in certain stations in Kenya and Nyasaland, are allowed five (or two and a half) days' leave in respect of each month of service instead of six (or three) days' leave respectively. In Somaliland special leave regulations exist which provide for an officer taking leave after a shorter tour of service than in other parts of East Africa. Free first-class passages are provided for the officer on first appointment and on leave, and in certain cases assistance towards family passages is given.

In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half-pay may be granted on special grounds. Up to the end of 1928 free passages are granted on first appointment and on leave, but the continuance of this privilege beyond that date is uncertain; but free passages on first appointment or transfer are granted permanently for officers with salary under £800 per annum.

In other Colonies outside Tropical Africa, subject to the necessities of the service, leave of absence on half salary may be granted after a period of three years' resident service without any special grounds. It may be given before the expiration of that period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months[3] in any two years. In British Guiana officers are allowed to accumulate full-pay leave at the rate of six weeks for each year's service up to six months, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay leave may be taken in addition to six months' full-pay leave.

On first appointment an officer whose salary and fees together do not exceed £800 a year will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. An officer taking leave out of the Colony has in most cases to provide his own passages.

Pensions.—East Africa.—Officers on the pensionable establishment retire on attaining the age of 50 years or after 20 years' East African service, whichever is earlier; but they may be retained in the service, with their own consent, for such further period as the Government may recommend. Earlier retirement in the event of ill-health is also provided for. Pension is computed at one-sixtieth of pensionable emoluments—i.e., salary and value of free quarters[4]—at the time of retirement, two years' service being reckoned as three years for this purpose, subject to an average of emoluments for the last two years before retirement instead of the actual emoluments at the time of retirement being taken as the basis for calculation in certain circumstances.

---

[2] £1 Egyptian (of 100 piastres) is equivalent to £1 0*s*. 6*d*. sterling.

[3] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years.

[4] The value of free quarters for pension purposes is taken as 15 per cent. of the minimum salary of the grade in which an officer is serving at the time of retirement.

Other Colonies.—In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service; otherwise he must have attained the age of 55. For ten full years' resident service fifteen-sixtieths of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half-pay as half service. In a few cases the retiring age is 60 and the pension after ten years' service is ten-sixtieths instead of fifteen. In the Straits Settlements and Malay States, an officer may, with the consent of Government, retire at age 50. Pensions are calculated on a basis of length of service in months instead of years.

WEST AFRICAN MEDICAL STAFF.

Applicants for appointment as medical officers in the West African Medical Staff (the higher grades will usually be filled by promotion from the lower) must be British subjects of European parentage and between 23 and 35 years of age; preference is given to candidates who are over 25 years of age. Applicants must possess a complete double qualification, and must be on the Medical Register. Passages for wives and children are not provided by the Government, and houses for the wives of junior medical officers are rarely available. Officers are not allowed to take their wives and young children out with them until they have acquired experience of the local conditions and have obtained the sanction of the Governor; and permission to bring out young children will only be given in the most exceptional circumstances.

Candidates whom it is proposed to select for appointment will have to be medically examined by one of the medical advisers of the Colonial Office (or, in the case of those residing in a Colony, by a medical officer appointed by the Colonial Government), and no appointment will be made unless the candidate is declared to be physically fit for service in West Africa. Candidates are allowed to express a preference for any particular Colony or Protectorate, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary to any other West African Colony or Protectorate at the discretion of the Secretary of State. Candidates who wish to be posted to the Northern Provinces of Nigeria should be able to ride. Transfers from one Colony or Protectorate to another will be made as seldom as possible. Candidates should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred elsewhere, as the number of such transfers is exceedingly small.

Officers of the West African Medical Staff who may be transferred to pensionable appointments under the Crown elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided that they have been members of the staff for at least 12 months. Every officer selected for appointment is required to have himself revaccinated before proceeding to West Africa, unless one of the medical advisers of the Colonial Office certifies in any particular case that this is unnecessary.

Instruction in Tropical Medicine.—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction for three to five months, either at the London School of Tropical Medicine, Endsleigh-gardens, Euston-square, N.W. 1, or at the Liverpool School of Tropical Medicine, University, Liverpool. The cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £3 a week will be paid to them monthly in arrear for this purpose. A daily allowance of 5s. (but no salary) will be paid to each candidate monthly in arrear during the course, and may be continued subsequently up to the date of embarkation. He will be bound to refund them (1) if he declines to accept an appointment in any of the Colonies or Protectorates for which he may be selected by the Secretary of State; (2) if he fails to obtain a certificate in regard to progress and efficiency, or (3) if he relinquishes the West African Service for any other reason than mental or physical infirmity, or is removed for misconduct, within three years of the date of his arrival in West Africa.

If at the end of the session there exists no vacancy in the Staff to which a candidate can be appointed, he will be placed in a Reserve and granted an allowance at the rate of £200 a year until the occurrence of a vacancy.

Leave of Absence.—European officers in West Africa may be granted vacation leave on full salary not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United Kingdom, and, if the officer is returning to West Africa for further service, the time necessarily taken on the journey from the United Kingdom to the Colony. Vacation leave may be granted without any special grounds after 18 consecutive calendar months of residential service in West Africa. An officer will not be required to serve a tour of more than 24 consecutive calendar months' residential service except in special circumstances; and the Governor may grant vacation leave to any officer at any time after he has completed 12 consecutive calendar months' residential service. Vacation leave on full salary may also be granted to an officer if he is invalided from West Africa after less than 12 consecutive calendar months' residential service, and sick leave on full salary may be granted for any period not exceeding six calendar months.

Appointments and Salaries.—The Medical Services of the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria (Southern and Northern Provinces)—form one service under the name of the West African Medical Staff. All the medical officers for the service are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. The grades and emoluments of the Staff are at present as follows:—

The Director of the Medical and Sanitary Service, Nigeria, receives a salary of £1800 a year, with a duty allowance at the rate of £360 a year. The Director of Medical and Sanitary Service in the Gold Coast receives a salary of £1600 a year, with a duty allowance at the rate of £320 a year. The Director of Medical and Sanitary Service in Sierra Leone receives a salary of £1400 a year, with a duty allowance at the rate of £280 a year. The Deputy Director of Medical and Sanitary Service, Nigeria, and the Deputy Director of Sanitary Service, Nigeria, receive salaries of £1500 a year, with duty allowances at the rate of £300 a year. The Deputy Director of Medical and Sanitary Service, Gold Coast, receives a salary of £1400 a year, with duty allowance at the rate of £280 a year. Assistant Directors Medical Service: There are nine appointments on this grade, six in Nigeria, two in the Gold Coast, and one in Sierra Leone. The salary is at the rate of £1300 a year, with duty allowance at the rate of £200 a year. The Assistant Director of Sanitary Service, Nigeria, the Deputy Director of Sanitary Service in the Gold Coast and the Deputy Director of Sanitary Service in Sierra Leone receive salary at the rate of £1300 a year, with duty allowance at the rate of £200 a year. Specialists: The number of these appointments is not fixed, officers of outstanding professional merit being eligible for appointment. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. After five years' approved service as such, the specialist officer is eligible to receive a salary at the rate of £1400 a year, with duty allowance at the rate of £280 a year. There are at present five officers appointed specialists in Nigeria and three in the Gold Coast. Senior Medical Officer: There are twenty appointments of this grade, with salary at the rate of £1000 a year, rising by annual increments of £50 to £1150 a year, and seniority allowance at the rate of £100 a year. The Senior Medical Officer, Gambia, is allowed "staff pay" of £150 a year, in addition to duty allowance, but he is debarred from private practice. Senior Sanitary Officer: There are six appointments of this grade, with salary at the rate of £1050 a year, rising by annual increments of £50 to £1200 a year, and a duty allowance at the rate of £210 a year. Medical Officer: The salary attached to this grade is at the rate of £600 a year, rising by annual increments of £30 to £720 a year. Then, if confirmed in the appointment, £720 a year, rising by annual increments of £40 to £960, with seniority allowance at the rate of £72 a year. Before passing £800, medical officers are required to take a special course of study for three months. If they obtain satisfactory certificates at the end of the course they draw their further increments up to £960 a year.

A medical officer who has served for three years on the maximum salary of this scale (£960) without obtaining promotion is eligible, if recommended by the Governor, to be placed on the scale £1000–£50–£1150, with £100 seniority allowance (as for Senior Medical Officers).

Special Appointments.—The Director of the Medical Research Institute, Lagos, and the Director of Research, Accra, receive a salary of £1300 a year, with a duty allowance of £260 a year, rising after five years' approved service to a salary at the rate of £1400 a year and duty allowance at the rate of £280 a year. Salary at the rate of £800 a year, rising by annual increments of £40 to £960 a year is attached to about 14 posts (those of assistant at the Medical Research Institute, Lagos, and medical officers of health at various places), irrespective of the seniority of the officer holding the appointment. In addition to the seniority allowance (£72 a year), staff pay at the rate of £150 a year is also attached to these posts; and the holder of the appointment draws half of the staff pay during leave of absence, the remainder being drawn by his locum tenens. The holders of these appointments are not allowed private practice.

Duty allowances, seniority allowance, and staff pay are not pensionable emoluments.

Increments.—Increments to salaries are payable only when the service of an officer during the period of employment qualifying for increment is approved.

Payment of Salaries.—Information as to the payment of officers' salaries or of monthly remittances to persons in England may be obtained from the Crown Agents for the Colonies, 4, Millbank, S.W. 1. All allowances are paid locally.

All officers of the staff, except directors, deputy directors, assistant directors, senior sanitary officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the faithful and efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at the majority of stations, and no guarantee can be given that an officer will be posted to a station in which he will be able to practise privately. As a general rule, and subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the Staff.

Pensions and Gratuities.—Pensions and gratuities on retirement from the service are granted in accordance with the law and regulations of each individual Colony.

Fuller information can be obtained from the Private Secretary, Colonial Office, Whitehall, London, S.W. 1.

SUDAN MEDICAL SERVICE.

This service is responsible for carrying out civil medical work and public health duties in the Sudan. The staff consists of: (*a*) Director, Sudan Medical Service—pay £1500–£1800; (*b*) senior physician—pay £1200–£1750—and (*c*) senior surgeon—pay £1200–£1750—Khartoum and Omdurman Civil Hospitals; (*d*) medical officer of health, Khartoum Province and assistant director—pay £1200 (this post is of a temporary nature and the terms and nature of the duties are subject to alteration); (*e*) a number of (at present 10) senior medical inspectors and medical inspectors who are all British. Their pay commences at £720 and rises, subject to the recommendation of the director, by five biennial increases to £1080 and thence, after three years at £1080, to £1200. Senior medical inspectors are eligible for promotion by selection to the four senior posts. Every medical inspector is appointed on probation for two years. If at the expiration of this time he is taken on the permanent service of the Government, his increase of pay is subject to passing such examination in Arabic as may be required by the regulations. (*f*) A number of medical officers trained at one of the Syrian medical schools. (*g*) A number of assistant medical officers, natives of the Sudan, who have been given a purely clinical training in one of the larger Sudan hospitals.

Among the attractions of the service is the annual leave of 90 days for every year's service which under ordinary circumstances may be granted every year, study-leave for some definite purpose, and two years granted towards pension to men with higher qualifications and experience. The ordinary pension for a medical inspector retiring after 20 years' service is approximately £500 a year. Private practice is limited to a few of the larger towns, but may be carried on so long as it does not in any way interfere with official duties. These duties include the charge of the medical and sanitary work of a province; acting as a consultant to the hospitals of the province or supervising smaller hospitals or dispensaries; initiating and supervising the medical and sanitary work of a province; the medical supervision of schools; the examination of candidates for Government service and pension; and the training of assistant medical officers and native sanitary overseers.

Vacant Appointments.—At the present moment there are vacancies for medical inspectors, who must be single, under 30 years of age, and who must have held a resident appointment (preferably house surgeon) to a large general hospital. Applications in writing only, with copies of recent testimonials, should be made to Dr. T. D. Acland, 19, Bryanston-square, W. 1, from whom and from the Secretaries or Deans of the principal medical schools, further particulars can be obtained.

SPECIAL DIPLOMAS.

DIPLOMA IN TROPICAL MEDICINE.

ALTHOUGH a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad. Systematic instruction for these diplomas is given at the Incorporated Liverpool School of Tropical Medicine (founded in 1898) and at the London School of Tropical Medicine, 5, Endsleigh-gardens, London, N.W. 1 (founded in 1899), which is a school of the University of London in the Faculty of Medicine.

University of Cambridge.—The examination for the Diploma in Tropical Medicine and Hygiene is divided into two parts. Part I. is held in Cambridge in April and Part II. in July in London. Candidates for Part I. are examined under the same regulations and in the same subjects as candidates for the Diploma in Public Health, but any qualification in medicine or surgery recognised by the proper authority of any country outside the British Dominions may be recognised. The subjects for Part II. are Medicine, Surgery, and Hygiene in their relation to Tropical Disease.

The examination will be partly in writing, partly oral, and partly practical or clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment). Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma (D.T.M. & H.) testifying to his knowledge and skill in tropical medicine and hygiene.

The fee for each part of the examination is £10 10s., and applications should be addressed to Mr. J. E. Purvis, Public Health Chemical Laboratory, Cambridge.

University of London.—The M.D. degree may be taken in tropical medicine at an examination held twice annually, for which a thesis may be submitted.

University of Liverpool.—The University grants a Diploma in Tropical Medicine. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The subjects of examination are (*a*) Tropical Pathology, Parasitology and Entomology; (*b*) Tropical and Applied Bacteriology; (*c*) Tropical Hygiene and Sanitation; (*d*) Tropical Medicine, including Ætiology, Symptoms, Diagnosis, and Treatment of Tropical Diseases. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. The fee for the full course of instruction is £21, with an extra charge of 10*s.* 6*d.* for the use of a microscope if required. Applications should be made to the Dean of the Medical Faculty, University of Liverpool. A diploma in Tropical Hygiene (D.T.H.) has recently been established. The subjects of examination are bacteriology, chemistry (including meteorology and climatology), entomology, protozoology, and helminthology; tropical sanitation (including sanitary engineering); practical sanitation. Fee for the course, £15. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The diploma of D.T.M. & H. Eng. is awarded on the results of an examination held twice yearly, in February and July. Candidates must possess a registrable qualification, and produce evidence of having attended (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine in a recognised institution during not less than five months, (2) clinical practice of a recognised hospital for the same period. Conditions of study may be modified in the case of candidates of special experience. Fee for admission to the examination, £9 9s., 14 days' notice of entry to the Secretary, Examination Hall, Queen-square, London, W.C. 1.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

THE Universities of Cambridge, London, Durham, Leeds, Manchester, and Edinburgh, and the Conjoint Board of the R.C.P. Lond. and R.C.S. Eng. now grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses; the details on these points can be obtained from the various examination bodies.

In London, courses of instruction for the Diploma in Psychological Medicine are given at the Maudsley Hospital, Denmark Hill, which has recently been definitely recognised as a school of the University of London. The course consists of two parts, and is adapted for the diploma of the Conjoint Board, the University of London, or the University of Cambridge. The fee for the whole course (Parts I. and II.) is 15 guineas, or for either part separately 10 guineas.

Appointments as clinical assistants are obtainable at the Maudsley Hospital. The holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. The appointments and other facilities for clinical experience are open to qualified medical practitioners apart from the courses of instruction. Inquiries as to lectures should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E. 5; and as to clinical facilities, to the Medical Superintendent at the same address.

A course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by the various Universities, is held at Bethlem Royal Hospital twice annually, during the spring and autumn. The fee for the full course is 15 guineas; for Part A separately 10 guineas, and for Part B separately 10 guineas. Communications should be addressed to the Physician-Superintendent, Bethlem Royal Hospital, London, S.E. 1. In addition clinical instruction in psychological medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 o'clock. The fee for post-graduates is 5 guineas for three months' attendance, but a reduction is made to those who attend the diploma course.

DIPLOMA IN OPHTHALMIC MEDICINE.

SPECIAL diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford.—The diploma in ophthalmology (D.O.) is granted to registered medical practitioners after passing an examination, held annually in July, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' recognised hospital course. Further information regarding these requirements may be obtained from the Dean of the School of Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The Conjoint Board grants the D.O.M.S. after an examination held in two parts, twice yearly in January and July. Part I. comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics. Part II. comprises optical defects, ophthalmic medicine and surgery, and pathology with special reference to ophthalmology. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of a year of special study of ophthalmology after obtaining a registrable qualification. Fee for admission to each part, £6 6s.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

THIS Diploma is granted by the University of Cambridge. It is only open to those who hold a medical qualification, and includes a course of lectures and practical work in Physics (Part I.), and in Radiology and Electrology (Part II.). Attendances at the necessary course of lectures in both subjects and, in addition, six months' clinical experience in an adequately equipped hospital recognised by the Committee are essential. The whole course of study takes six months, the lectures, practical work, and hospital attendance running concurrently. The Courses carried out by the University of Cambridge are at present arranged to begin early in January. Three months are spent in Cambridge doing the lectures and practical work in Part I., attending the systematic lectures in Part II., and the practice of Addenbrooke's Hospital, where there is a fully equipped and up-to-date X ray and Electrological Department. The remaining three months can be completed at any recognised hospital, but special arrangements are made for students to continue their studies in London, where demonstrations at various hospitals are arranged in order to give a wide experience. In addition, an independent course is arranged by the British Association of Radiology and Physio-Therapy. This Course is held entirely in London, but is recognised by the University as qualifying for the examination, and begins early in October. Further particulars as to the Cambridge

Course can be obtained from Dr. F. Shillington Scales, Medical Schools, Cambridge, and of the London Courses from Dr. Stanley Melville, at the Offices of the B.A.R.P., 12, Stratford Place, London, W. 1.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.

THE Conjoint Board R.C.P. Lond., R.C.S. Eng., *grants the D.L.O.* after an examination held in two parts, twice yearly, in June and December. Part I. comprises anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus. Part II. comprises the medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus, and the recognition and use of special instruments and appliances. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of one year of special study of the diseases of the ear, nose, pharynx, and larynx, after obtaining a registrable qualification. The fee for admission to each part is 6 guineas.

DIPLOMA IN TUBERCULOUS DISEASES.

A DIPLOMA in Tuberculous Diseases is given by the University of Wales. Candidates must possess a medical qualification registrable for practice in Great Britain and Ireland, and be not less than 25 years of age, and either (Category A) have held, for a period of not less than five years, whole-time appointments for work in tuberculosis; or (Category B) have held a registrable qualification to practise for at least one year, and presented (*a*) a certificate of satisfactory pursuance of a course of consecutive post-graduate study of the clinical and epidemiological aspects of tuberculosis of six months' duration at a recognised university, medical school, or hospital where such a course is given; or, alternatively, a certificate of one year's post-graduate work as a whole-time member of the staff of a tuberculosis hospital, sanatorium, or dispensary approved by the Ministry of Health, signed by the representative of the authorities for whom the work was performed or by the administrative medical officer concerned; (*b*) a certificate of satisfactory pursuance of a course of consecutive post-graduate practical study of the Pathology and Bacteriology of Tuberculosis of three months' duration at a tuberculosis laboratory or a recognised general laboratory where such a course is given; (*c*) a certificate of three months' satisfactory attendance at a tuberculosis institute or dispensary. The courses may be taken concurrently.

The examination is divided into two parts. The fee for examination is £10 10*s*. Applications should be made to the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 15th.

THE DEGREE OF M.D. BRUSSELS.

To obtain the degree of M.D. Brussels all foreign graduates must submit their degrees or diplomas for consideration to the Secretary of the University of Brussels. According to the standard of the qualification, a period of one, two, or three years must be spent by the candidate in attending lectures, clinics, and practical work at Brussels, in the University, before permission is given to enter for examinations. The standard of this degree, known as the "Scientific" M.D., is equivalent to that of the "legal" M.D. obtainable from the University only after seven years' residence, but it does not carry with it the right to practise in Belgium. The examinations are conducted orally in French. Further information may be obtained from the Hon. Secretary of the Brussels Medical Graduates' Association, Dr. Arthur Haydon, 10, Sussex-gardens, Talbot-square, Hyde Park, London, W. 2.

DIPLOMA IN PUBLIC HEALTH.

As usual we include in the Students' Number of THE LANCET an epitome of the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, hygiene or State medicine, as this discipline is variously called. Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council from 1902 to 1922. The new regulations, which came into force in 1923, extend the period of study and postpone the granting of a diploma until at least two years from qualification.

Conjoint Board of the R.C.P. Lond. and R.C.S. Eng.—New regulations came into force on Jan. 1st, 1924, which apply to all candidates who have not commenced bonâ-fide study of Public Health in accordance with the above regulations before that date. They are as follows: The Examination consists of two Parts. Part I. will be held in the months of January and June, and Part II. in the months of January and July in each year. Candidates may enter for Parts I. and II. separately or at the same time, but they must pass Part I. before proceeding to Part II. The Examination in each part will be written, oral, and practical. Part II. will include a practical examination in Infectious Diseases, Food Inspection, and Inspection of selected Premises. The Fee for admission to each Part of the Examination, which must be paid three days before that part commences, is £10 10*s*., except in the case of Candidates who possess the Licence, Membership, or Fellowship of the Royal College of Physicians of London, or the Membership or Fellowship of the Royal College of Surgeons of England, who will be required to pay £6 6*s*. only for each part. Candidates who fail to satisfy the Examiners in either part may present themselves again at the next Examination on payment of the same Fees. Candidates intending to present themselves for either part of the Examination must give 14 days' notice in writing to the Secretary, at the Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

Candidates will be admissible to Examination in Part I. on producing evidence:—

1. Of being in possession of a registrable qualification in Medicine, Surgery, and Midwifery.

2. Of having attended during a period of not less than five months at an Institution recognised by the Examining Board in England, practical instruction in (*a*) Bacteriology and Parasitology (including Medical Entomology) especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical laboratory work. (*b*) Chemistry and Physics in relation to public health, during 90 hours, of which not less than 70 hours have been occupied in practical laboratory work. (*c*) Meteorology and Climatology in relation to public health, during not less than 10 hours.

Candidates will be admitted to Part II. of the Examination on producing evidence:—

1. Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery during not less than two years, of being registered by the General Medical Council, and of having completed the curriculum for the Diploma extending over a period of 12 calendar months subsequent to the attainment of a registrable qualification.

2. Of having attended, after obtaining the registrable Qualification, instruction during not less than 80 hours at an Institution recognised by the Examining Board in England in the following subjects:—(*a*) The Principles of Public Health and Sanitation for not less than 30 hours; (*b*) Epidemiology and Vital Statistics for not less than 20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours; (*d*) Sanitary Construction and Planning during not less than 10 hours.

3. Of having attended for three months the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England and of having therein received instruction in the methods of administration. The Certificate

must state that the candidate has attended on one or more days in each week of the three months, that each attendance was of two hours' duration, with a total attendance of 60 hours.

4. Of having been engaged during a period of not less than six months in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a Medical Officer of Health, and of having received, from such officer or other competent Medical Officer during not less than three hours on each of 60 working days, practical instruction in those duties and also those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for children of school age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk.

The above certificate (4) must be obtained from a Medical Officer of Health who devotes his whole time to public work, or from a Medical Officer of Health of a Sanitary Area having a population of not less than 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

University of Oxford.—An examination, conducted partly in writing, partly vivâ voce, and in each subject partly practical, is held in Michaelmas and in Trinity Term in the following subjects:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £10 for each part. Successful candidates are entitled to receive the Diploma in Public Health.

The First Part of the examination will comprise (*a*) written papers of three hours each in (I.) Chemistry and Physics, and (II.) Pathology and Bacteriology; (*b*) a three hours' practical and vivâ voce examination in Chemistry and Physics; (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

The Second Part of the Examination will consist of the following parts:—(*a*) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and the Laws relating to Public Health); (*b*) a practical and vivâ voce examination in General Hygiene; and (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce certificates (1) of Laboratory Work in Chemistry, Physics, Meteorology, and Climatology as applied to Hygiene, and (2) of having had Practical Instruction in Bacteriology and Parasitology and the Pathology of the Diseases of Animals transmissible to Man.

Candidates in Part II. will produce the following further certificates: (3) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration.

All the above degrees are now open to Women Students, and particulars of Scholarships, &c., may be obtained from the Principals of the various Ladies' Colleges. The names of candidates for the Diploma in Public Health must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford. Applications for any further information should be addressed to the Dean, Department of Medicine, Museum, Oxford.

University of Cambridge.—Two examinations in so much of State medicine as is comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) Part I. of the examination; or (2) Part II. of the examination. Every candidate will be required to pay a fee of £10 10*s*. before admission or readmission to *either part* of the examination. Candidates must before admission to either part of the examination produce evidence of having satisfied the regulations applicable to Part I. and Part II.

For Part I. of the examination courses of lectures and laboratory instruction are given in the University on Hygiene, Chemistry, &c., and on Bacteriology and Parasitology. For Part II. the Medical Officer of Health for Cambridge gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital, and the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology. There are also special courses in Vital Statistics, Tuberculosis Service, Venereal Diseases Service, Industrial Hygiene, Maternity and Child Welfare. These courses are open to non-members of the University.

A special Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England.

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Public Health Chemical Laboratory, Cambridge.

University of London.—Candidates for the M.D. Degree may offer State Medicine as a subject in which to graduate. The regulations have been revised and may be obtained *on application* to the Principal Officer, University of London, South Kensington.

University of Durham.—The Degree of Bachelor of Hygiene (B.Hy.) and the Diploma in Public Health (D.P.H.).—No candidate is admitted to the final examination for the Degree of B.Hy. unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognised University, and no candidate is admitted to the final examination for the D.P.H. unless he is a registered medical practitioner, of not less than two years' standing. The course of study for the B.Hy. and D.P.H. extends over a period of not less than 12 calendar months, subsequent to the attainment of a registrable qualification. Candidates for the B.Hy. must attend this course at the University of Durham; candidates for the D.P.H. may attend it at the University of Durham, or at any medical school or institution which is recognised by the University. The examination for the diploma or degree is divided into two parts. A candidate must pass in all the subjects of Part I. before being admitted to examination for Part II. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. The examination for Part I. is practical, written, and oral, and includes the following subjects: Bacteriology and Parasitology (including medical entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. Candidates are not admitted to examination for Part I. until after they have completed the prescribed courses of instruction in the subjects thereof. The examination for Part II. includes Hygiene and Sanitation (including sanitary construction), Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination is written and oral, and includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises—Dwellings, Factories, Workshops, Schools, &c. Candidates are not admitted to examination for Part II. until after they have completed the prescribed courses of instruction in the subjects thereof. The fee for the examination for the degree of B.Hy. is £10 10*s*. and for the degree £6 6*s*. The fee for the examination for the Diploma in Public Health is £10 10*s*. and for the diploma £3. Doctor of Hygiene

(D.Hy.): Candidates must be Bachelors of Hygiene of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of Public Health. The fee for the examination is £20 and for the degree £10.

Victoria University of Manchester.—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part of the examination is £8 8*s*., and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £4 4*s*. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examination will begin about the middle of July and the middle of October in each year. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice. An examination for a Diploma in Bacteriology is held for graduates in science or medicine who have attended prescribed courses for at least one academic year; candidates must present a satisfactory thesis on an approved subject.

University of Birmingham.—Under the revised rules and regulations of the General Medical Council the University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. The examinations will be held in the months of March and June and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £6 5*s*. Medical Officers of the Royal Navy who have attended courses in Hygienic Chemistry, Bacteriology, and Public Health at the Naval Medical School, Greenwich, will be admitted to Part I. examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied Chemistry and Bacteriology at the Staff College and pursued the further course of study approved by the General Medical Council.

University of Liverpool.—The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The courses may be taken out at any time, and students are allowed to work daily in the laboratories. Composition fee for M.H. £40 a session, and D.P.H. £45 a course.

University of Leeds.—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical. Candidates must pass in Part I. before being admitted to Part II. Fees.—The fee for each part is £6 6*s*., and for any subsequent examination in the same part £4 4*s*. Instruction in Entomology and Meteorology is given in the first term, and in Sanitary Chemistry and Bacteriology in the second and third terms. Practical work under arrangement with the Leeds City Council. Prospectus can be obtained from the Academic Sub-Dean of the Medical School.

University of Bristol.—Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than two years' standing as such, and shall have passed the examination prescribed by regulation. The examination is divided into two parts.

University of Wales.—Candidates for the Diploma in Public Health, the curriculum for which extends over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification, must produce evidence of having attended for not less than five months at the Welsh National School of Medicine or at an institution approved by the Court, practical instruction in Bacteriology and Parasitology, Chemistry and Physics, and Meteorology and Climatology in relation to Public Health. Candidates must also satisfy the examiners that they have received instruction approved by the University in the Principles of Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. The candidate must also produce evidence that he has attended for three months on the clinical practice of a hospital for infectious diseases containing not less than 100 beds, and has received therein instruction in the methods of administration, and that he has for a period of not less than six months been engaged in acquiring a practical knowledge of the duties, routine and special, of a public health administration under the supervision of a medical officer of health. The examination for the diploma is divided into two parts, Part I. and Part II., each of which extends over not less than two days. A candidate must pass in all the subjects of Part I. before being admitted to Part II. of the examination. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. Part I. of the examination is practical, written and oral, and includes Bacteriology and Parasitology (including Medical Entomology); Chemistry and Physics, and Meteorology and Climatology in relation to Public Health. Candidates may not be admitted to Part I. of the examination until they have been certified as having pursued the prescribed courses of instruction in the subjects thereof. Part II. of the examination, which is written and oral, includes: Hygiene and Sanitation (including Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. No candidate can be admitted to Part II. of the examination until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, Surgery, and Midwifery, which qualification must be registered before admission to Part II. of the examination. An examination in each part will be held annually, in June. Notice of candidature, together with the fee of six guineas for either part of the examination, must be sent to the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 15th.

University of Edinburgh.—Two degrees in Science are conferred in the Department of Public Health by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. A Diploma in Tropical Medicine and Hygiene is also granted. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a recognised University, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University;

they must also have attended courses of instruction in Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than 18 months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £4 4*s.* for the First and £5 5*s.* for the Second B.Sc. Examinations, and £15 15*s.* for the degree of D.Sc.

University of Aberdeen.—Every candidate for the Diploma in Public Health must be a graduate in medicine of the University of Aberdeen, or of any other University whose medical degrees are recognised as qualifying for registration by the General Medical Council of the United Kingdom. No candidate will be admitted to the Final Part of the Examination for the Diploma until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, which qualification shall have been registered before such admission. The whole of the prescribed curriculum of study must be undertaken after the candidate has obtained a registrable qualification in medicine, and shall extend over not less than twelve calendar months. At least one academic term must be spent at the University of Aberdeen. Every candidate shall produce evidence of having complied with the following requirements in respect of study and training:—1. Practical instruction in the following subjects within a laboratory or laboratories approved by the University: (*a*) Bacteriology and Parasitology (including Medical Entomology), in relation to diseases of man and diseases of lower animals transmissible to man—at least 180 hours, of which not less than 150 shall be occupied in practical laboratory work; (*b*) Chemistry and Physics, in relation to Public Health—at least 90 hours, of which not less than 70 shall be occupied in practical laboratory work; (*c*) Meteorology and Climatology, in relation to Public Health—at least 10 hours; such instruction to extend over not less than five months or two academic terms. 2. A course or courses of instruction extending over not less than 80 hours dealing with: (*a*) The Principles of Public Health and Sanitation—30 hours; (*b*) Epidemiology and Vital Statistics—20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services)—20 hours; (*d*) Sanitary Construction and Planning—10 hours; such course or courses to be given at an institution or by a teacher or teachers approved by the University. 3. Practical instruction, clinical and administrative, within a recognised hospital for general infectious diseases; such instruction to extend over three months, and to include 30 daily attendances of not less than two hours in each week. 4. Practical instruction and experience, during not less than six months (including attendance of at least three hours on each of sixty working days) in the duties, routine and special, of public health administration, under the supervision of a medical officer of health, who shall certify that the candidate has received from this officer or other competent medical officer, practical instruction in these duties, and also in those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. The medical officers of health recognised for this purpose by the General Medical Council are: (*a*) a medical officer of health who devotes his whole time to public health work; or (*b*) the medical officer of health of a sanitary area having a population of not less than 50,000; or (*c*) in Ireland, the medical superintendent officer of health of a county or county borough having a population of not less than 50,000. The examination for the diploma is divided into two parts, each of which extends over not less than three days. The following are the fees payable for the courses of instruction given within the University: Lecture Course or Courses, £4 4*s.*; Laboratory Instruction, £14. The examination fee is £8 8*s.*, which is payable as follows:—£4 4*s.* for Part I., and £4 4*s.* for Part II. The fees for external instruction amount approximately to £11 11*s.*

University of Glasgow.—Degree of B.Sc. in Public Health.—Candidates must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose by the University Court. Candidates must produce evidence (1) that, after they have obtained a registrable Degree in Medicine, a period of not less than two years has elapsed; (2) that, after they have obtained a registrable degree in Medicine, they have, during a period of not less than 21 calendar months, pursued the course of work and instruction prescribed, and have satisfied the examiners in the prescribed examinations. There are two examinations. Part I. includes the following subjects: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health; (iv) Higher Chemistry in relation to Public Health; (v) Physics and Geology. A candidate must pass in the subjects marked (i), (ii), and (iii) of Part I. at one examination. Part II. includes the following subjects: (vi) Hygiene and Sanitation (including Sanitary construction); (vii) Epidemiology and Infectious Diseases; (viii) Sanitary Law and Vital Statistics; (ix) Public Health Administration; (x) Applied Hygiene. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like. The examination in Applied Hygiene may be on a selected subject professed by the candidate. A candidate must pass in the subjects marked (vi), (vii), (viii), and (ix) of Part II. at one examination. *Diploma in Public Health (D.P.H.).*—Candidates for this Diploma must be legally qualified medical practitioners who are matriculated students of the University. A period of not less than two years must elapse between the attainment by the candidate of a registrable medical qualification, and his admission to the final examination (Part II.) for the Diploma. The candidate must, during a period of not less than 12 calendar months, subsequent to his attainment of a registrable medical qualification, pursue the course of work and instruction prescribed, and pass the prescribed examinations. The examination, which is both written and oral, is divided into two parts, Part I. and Part II., each of which extends over not less than two days. No candidate is admitted to either part of the examination until he has completed the prescribed courses of instruction in the subjects of that part. No candidate is admitted to Part II. until he has passed in all the subjects of Part I., nor until after the lapse of not less than two years from the date of his obtaining a registrable medical qualification, nor unless he presents a certificate showing that his name and qualification have been duly registered in the Medical Register. Part I. includes: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health. A candidate must pass in all the subjects at one examination. Part II. includes: (iv) Hygiene and Sanitation (including Sanitary Construction); (v) Epidemiology and Infectious Diseases; (vi) Sanitary Law and Vital Statistics; (vii) Public Health Administration. A candidate must pass in all the subjects at one examination. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like.

University of St. Andrews.—The Diploma in Public Health is open to medical graduates of a University of the United Kingdom. The examination is in two parts. (1) (*a*) Bacteriology and Parasitology; (*b*) Chemistry and Physics; (*c*) Meteorology and Climatology. (2) Hygiene and Sanitation, Epidemiology and Infectious Diseases, Sanitary Law and Vital Statistics, Public Health Administration. Before admission to the first examination the candidate must have held his medical degree for one year, and before admission to the second examination for two years. Graduates in Medicine of the University of St. Andrews may take part of all of the qualifying classes in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University or medical school recognised by the University Court, but graduates of another University must spend at least eight out of the 12 months' curriculum in St. Andrews University. A complete course is given in United College, Dundee. The examination fee for each division is £5 5*s.*

University of Dublin (Trinity College).—The Diploma in Public Health is conferred, after examination, under the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least two years before the second part of the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, five months' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have received instruction in the following subjects: The principles of public health and sanitation; epidemiology and vital statistics; sanitary law and administration (including public medical services); sanitary construction and planning, must have studied, practically, outdoor sanitary work for six months under an approved officer of health, and must have attended for three months at a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification and his admission to the Final Examination for the Diploma. The curriculum extends over a period of not less than 12 calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Physics, Meteorology and Climatology, and Bacteriology and Parasitology. Part II. comprises the following subjects: Hygiene and Sanitation, Sanitary Law, and Vital Statistics, Epidemiology and Infectious Diseases, Public Health Administration. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (*a*) shall have received the degrees of M.B., B.Ch., and B.A.O. at least two years previously; (*b*) shall have pursued an approved course of study in the Faculty of Medicine; and (*c*) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

University of Belfast.—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The examination will be held in two parts, in March and in June. The first part of the examination will have reference to the general principles of sanitary science and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The fee for each part is 1 guinea.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. Candidates must have attended not less than four calendar months' practical instruction in Chemistry and Bacteriology in a recognised laboratory or laboratories, must have studied outdoor sanitary work for six months under a medical officer of health or other sanitary officer; and must give evidence of attendance for three months at the practice of a Hospital for Infectious Diseases, at which he has received instruction in the methods of administration. The examination consists of two parts, and candidates may enter for both at one period or for either separately. The First Part includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics and Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in May in Glasgow, and October in Edinburgh. The published regulations provide detailed synopses of the subjects of examination, *and intimation is made that the curriculum and examination will be adjusted to meet the requirements of the regulations of the General Medical Council which came into force on Jan. 1st, 1924.* Candidates applying for Regulations should state date of commencement of curriculum. The Registrar for Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and for Glasgow Mr. Walter Hurst, 242, St. Vincent-street.

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland.—Every candidate for the Diploma in Public Health must observe the following rules: 1. A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery and his admission to the Final Examination for a Diploma in Public Health. 2. The curriculum for a Diploma in Public Health shall extend over a period of not less than 12 calendar months subsequent to the attainment of a registrable qualification. 3. Every candidate shall produce evidence of having attended, during a period of not less than five months, at an institution approved by the Licensing Body granting the Diploma, practical instruction in—(*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; (*b*) Chemistry and Physics in relation to Public Health; (*c*) Meteorology and Climatology in relation to Public Health. At least 180 hours must be devoted to Course (*a*), of which not less than 150 hours shall be occupied in practical Laboratory work. At least 90 hours must be devoted to Course (*b*), of which not less than 70 hours shall be occupied in practical Laboratory work. At least 10 hours must be devoted to Course (*c*). 4. Evidence of having received, during not less than 80 hours, at an institution or from teachers approved by the Licensing Body granting the Diploma, instruction in the following subjects: (*a*) The Principles of Public Health and Sanitation; (*b*) Epidemiology and Vital Statistics; (*c*) Sanitary Law and Administration (including Public Medical Services); (*d*) Sanitary Construction and Planning. 5. Evidence that he has attended for three months on the clinical practice of a recognised Hospital for Infectious Diseases. 6. Evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a Medical Officer of Health. The examination for the Diploma is divided into two parts. The examination for Part I. includes Bacteriology and Parasitology (with Medical Entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. The examination for Part II. includes Hygiene and Sanitation (with Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination, which is written and oral, includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises—dwellings, factories, workshops, schools, &c.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but it is a distinct advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available.

THE DENTAL BOARD OF THE UNITED KINGDOM.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly-constituted Dental Board of the United Kingdom. The registration of dental students at the commencement of their dental studies, and the right of erasure of a name from the Dentists Register, remain with the Council, but the duty of inquiring into disciplinary cases rests with the Board, upon whose recommendations the Council acts.

The Dental Board consists of a chairman and 12 members. The following are the names and sources of appointment of the members: Chairman of the Board, Rt. Hon. F. Dyke Acland, appointed by the Privy Council. Members of the Board: Mr. L. G. Brock, C.B., appointed by the Minister of Health; Mr. A. Young, appointed by the Scottish Board of Health; Mr. J. H. Stirling, appointed by the Governor-General of Northern Ireland; Sir Holburt Waring, M.S., F.R.C.S.; Sir James Hodsdon, K.B.E., F.R.C.S. Edin.; Mr. T. Sinclair, C.B., F.R.C.S., M.P., appointed by the General Medical Council; Mr. W. R. Ackland, M.D.S., M.R.C.S.; Mr. W. H. Dolamore, L.D.S., M.R.C.S., elected as Direct Representative by the qualified dentists practising in England and Wales; Mr. W. Guy, L.D.S., F.R.C.S., elected as a Direct Representative by the qualified dentists practising in Scotland; Mr. J. J. Andrew, L.D.S., elected as Direct Representative by the qualified dentists practising in Ireland; Mr. W. F. Bowen and Mr. F. Butterfield elected as Direct Representatives by registered dentists not being qualified dentists. Treasurers of the Board, Sir Holburt Waring and Mr. W. H. Dolamore. Registrar of the Board, Mr. N. C. King.

The offices of the Board are at 44, Hallam-street, London, W. 1, adjoining the offices of the General Medical Council.

REGISTRATION OF DENTAL STUDENTS.

The following are the General Medical Council's Regulations in regard to the registration of dental students which came into force on Jan. 1st, 1923.

The Council recommends that, subject to such exceptions as the Council may from time to time allow, every dental student at the commencement of his studentship should be registered in the manner and under the conditions hereinafter set forth.

1. The registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and is subject to the same regulations as regards age and preliminary examinations; but in the case of dental students professional study may commence by pupilage with a registered dental practitioner.

2. Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in mechanical dentistry (see No. 3 below).

3. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school.

4. Two years' bona-fide apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study.

5. The necessary instruction in dental mechanics, or any part of it, may be taken by the dental student either before or after his registration as a student. When a student can show evidence of regular pupilage in dental mechanics to a registered practitioner, prior to the passing of the prescribed preliminary and scientific examinations, he may be allowed to antedate his registration for a period not exceeding one year prior to the passing of these examinations (see No. 3 above).

EXAMINING AND TEACHING BODIES IN DENTISTRY.

The list of the Examining Bodies in Dentistry which grant diplomas or degrees in this subject and the regulations for obtaining these qualifications will appear in a guide to teaching institutions in dentistry at a later date.

In addition to facilities provided by the various Universities, Colleges, and Faculties, a number of dental courses are available. In London at the Royal Dental Hospital (School of Dental Surgery), Leicester-square, at University College Hospital Dental School, and at the Dental Departments of Guy's Hospital and of the London Hospital. In the provinces at the Birmingham, Manchester, and Newcastle-on-Tyne dental hospitals. In Scotland at the Incorporated Edinburgh Dental Hospital, the Incorporated Glasgow Dental Hospital, and the Dental Department of Glasgow Royal Infirmary. In Ireland at the Incorporated Dental Hospital of Ireland, Dublin. Dental study may be commenced also at any of the following schools: Birmingham Dental Hospital, Bristol Royal Infirmary and General Hospital, Dundee Dental Hospital, Leeds Dental Hospital, Liverpool Dental Hospital, and Sheffield Royal Hospital.

MINISTRY OF HEALTH APPOINTMENTS.

THE Minister of Health appoints medical officers of the Ministry in various parts of England and Wales in connexion with the National Health Insurance Medical Service. The duties of these officers include those of deputy to the Regional Medical Officer in the work carried out by the latter: (*a*) As Medical Referee in cases of insured persons referred for a second medical opinion on questions of incapacity for work, or of restoration of working capacity; (*b*) in assisting in the administration of the Insurance Medical Service.

Residence.—Medical Officers are required to reside in the area from time to time assigned to them.

Remuneration.—The rate of remuneration is £800 per annum, rising by annual increments of £30 to a maximum of £1100. No cost of living bonus is payable in addition thereto, but officers appointed to this scale will be established Civil Servants with the usual pension rights.

Successful candidates, who are considered to possess exceptional or special qualifications, may be allowed to enter the scale at a commencing salary of £850 per annum. Above the grade of Deputy Regional Medical Officer, there are at present 33 posts of Regional Medical Officers (30 in England and 3 in Wales) rising to a maximum of £1400 a year inclusive, and four posts of Divisional Medical Officers rising to a maximum of £1600 a year inclusive. The above numbers are, however, subject to revision from time to time as the exigencies of the Service may determine. When vacancies are to be filled among the Regional Medical Officers, preference will be given to those who have given satisfaction as Deputy Regional Medical Officers.

In England application should be made to the Secretary, Ministry of Health, Whitehall, London, S.W. 1, and in Wales to the Secretary, Welsh Board of Health, City Hall, Cardiff. Letters of application should be marked in bold letters, "Medical Officer."

PRISON MEDICAL SERVICE.

CANDIDATES for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment may be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. 1. In the smaller prisons the medical officership is part-time, and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer, Class II., and from the seniors of this rank the Medical Officers, Class I., are selected as vacancies occur. The pay of the whole-time prison medical staff is as follows: Medical Officer, Class II., £350, rising by annual increments of £20 to £600, making the pay at present with bonus £504 14*s.* to £801 11*s.*; Medical Officer, Class I., £650, rising by annual increments of £25 to £800, plus bonus, making the pay £864 to £1023 9*s.* Unfurnished quarters are provided or an allowance in lieu is made. There are 12 full-time medical officers of Class I. and 13 Class II., and 23 part-time medical officers. The number of vacancies is never large and promotion is slow. In the case of a part-time medical officer, the population of the prison is the basis of fixing the salary, unless there are some special features justifying special consideration.

Obituary.

PERCIVAL LANGDON-DOWN, M.A., M.B., B.CH. CAMB.,

JOINT SUPERINTENDENT, NORMANSFIELD, MIDDLESEX.

Dr. Percival Langdon-Down, of Teddington-on-Thames, who died on August 19th, received his medical education at the London Hospital, proceeding to the degree of M.B., B.Ch. Camb., and holding the post of house surgeon at his hospital. He was the son of Dr. H. Langdon-Down, the founder of Normansfield, the well-known private institution for mentally defective cases. Together with his brother Reginald, Dr. Percival Langdon-Down carried on this work and was an authority on mental disorders. In addition, he took an active interest in public affairs. He first became a member of the local district council in 1900 and continued to represent the South Ward until his death. He was for several years chairman of the council and was its senior member, only four of those who were on it in 1900 being still alive. His value was early recognised and within a year of his election he was made chairman of the by-laws committee, a thorny subject on which he became a recognised authority. For many years he sat as a representative of the riparian districts of Teddington, Hampton, Hampton Wick, and Surbiton on the Thames Conservancy, and at the quarterly meetings of the representatives of these districts he was in the habit of presenting reports which were of the greatest value. He was keenly interested in the river and was a leader in the steps that were taken some years ago to obtain photographic and other records of the riverside. There were few movements set on foot for the good of Teddington which did not find in him an ardent and generous supporter. He took a great interest in the Cottage Hospital, of which his late father had been one of the medical attendants, and for some years he presided at the annual hospital meeting held at the Wesleyan Church by the brotherhood. He was one of the earliest members of the Teddington and Hampton branch of the League of Nations Union, of which he was the president. He was a vice-president of the Thames Valley Association of Cornishmen and Devonians. In his death all local interests, as well as the medical profession, have sustained a severe loss.

THE LATE DR. J. F. GORDON DILL.

WE regret to learn the death of Dr. J. F. Gordon Dill, consulting physician to the Royal Sussex County Hospital, which occurred at Hove on August 22nd last. A fuller notice will be published in an early issue of THE LANCET. He had been anxiously ill for some months and had undergone a serious operation, so that the end may have been expected by many of his numerous personal friends.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Aug. 31st.—11 A.M., Surgical Registrar: Surgical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Dr. Trevor Davies: Diseases of Women.

TUESDAY, Sept. 1st.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Dr. Dowling: Skin Dept.

THURSDAY.—12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Donald Armour: Operations. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 12 noon, Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

THE
Physiological Basis
OF
ATHLETIC RECORDS.

Being the Presidential Address to the Section of Physiology of the British Association.

BY PROF. A. V. HILL, O.B.E., Sc.D., F.R.S.

IN the study of the physiology of muscular exercise there is a vast store of accurate information, hitherto almost unexploited, in the records of athletic sports and racing. The greatest efforts and the most intense care have been expended in making what are really experiments upon these subjects, and the results obtained represent what may justly be described as a collection of natural constants of muscular effort in the human race. It is the purpose of this address to discuss certain aspects of the data available in connexion with various forms of racing, and to see how far physiological principles at present known underlie them.

SOURCES OF INFORMATION.

The most complete set of records available, for a great variety of sports, is to be found in "The World's Almanac and Book of Facts," published by the *New York World*. Much of the information here presented was obtained from the 1925 edition of that work; similar but less extensive data can be found in our own Whitaker's Almanack. In addition, various books on horse-racing, on swimming, and on rowing have been searched for suitable material. I will not deal further with the statistical analysis of the facts, beyond referring to an extremely interesting and suggestive collection of them given in a paper by A. E. Kennelly, entitled An Approximate Law of Fatigue in the Speed of Racing Animals, published in the Proceedings of the American Academy of Arts and Sciences (vol. xlii., p. 275, 1906).

FATIGUE AS THE DETERMINING FACTOR.

An important and interesting problem for any young athlete is presented by the question "how fast can I run some given distance?" The maximum speed at which a given distance can be covered is known to vary largely with the distance. What are the factors determining the variation of speed with distance? How far, knowing a man's best times at two distances, can one interpolate between them for an intermediate distance, or extrapolate for a distance greater or less? Obviously the answer to such questions depends upon the factor which in general terms we designate fatigue. Fatigue, however, is a very indefinite and inexact expression; it is necessary to define it quantitatively before we can employ it in a quantitative discussion such as this. There are many varieties of fatigue, but of these only a few concern us now. There is that which results in a short time from extremely violent effort; there is the fatigue, which may be called exhaustion, which overcomes the body when an effort of more moderate intensity is continued for a long time. Both of these may be defined as muscular. Then there is the kind which we may describe as due to wear-and-tear of the body as a whole, to blisters, soreness, stiffness, nervous exhaustion, metabolic changes and disturbances, sleeplessness, and similar factors, which may affect an individual long before his muscular system has given out. Of these three forms of fatigue the first one only is as yet susceptible of exact measurement and description. The second type may quite possibly come within the range of experiment at no distant date. The third type is still so indefinite and complex that one cannot hope at present to define it accurately and to measure it. Undoubtedly, however, all these types of what we call "fatigue" influence—indeed, determine—the results which are to be presented.

PRESENTATION OF DATA.

The data will be exposed in graphical form, and in every case the quantities plotted are the speed as ordinate and the time, or some function of the time, as abscissa. The reason for taking the *time* occupied in a race as one of our variables is simple; the problem before us, physiologically speaking, is, clearly, *how long can a given effort be maintained?* The length of time is given by the abscissa as the independent variable; the magnitude of the effort, or some function of it, as represented by the speed (that is, by the average speed over the race considered), is given as ordinate. It will be shown below, as Kennelly indicated in his paper, that the ideal way to run a race, possibly not from the point of view of winning it, but certainly from that of breaking the record for the distance, is to run it at constant speed. In those performances which have attained to the dignity of a world's record it is unlikely that this criterion has been to any very large degree neglected. Apart, therefore, from the fact that there is no speed of which we have any record except the average speed, we are probably not far wrong in using the average speed as a fairly exact measure, or at any rate as a function of the effort involved.

In one case only (Fig. 4) the time occupied in the race has been given on a logarithmic scale; no great virtue attaches to the logarithm, but if 75 yards and 100 miles are to be shown on the same diagram in a readable form it is necessary somehow to condense the abscissæ at the longer times.

RUNNING AND SWIMMING: SHORTER TIMES.

In Fig. 1 all the important world's records are presented, average speed against time, for men and women running and for men and women swimming. The crosses representing men rowing in an 8-oar boat will be discussed later. It is obvious in all four cases that we are dealing with the same phenomena, a very high speed maintainable for short times, a speed rapidly decreasing as the time is increased and attaining practically a constant value after about 12 minutes. There are no reliable records, in the case of swimming, for times of less than about 50 seconds, so that the curves cannot be continued back as far as those for running. There can, however, be no doubt that the curves for running and swimming are essentially similar to one another and must depend upon the same factors. In running, starting inertia is the cause of the initial upward trend of the curves; a maximum average velocity is attained in the case of men for about 200 yards, of women for about 100 yards; after that a rapid decrease sets in, ending only when the time has become 10 or 15 minutes, the distance two to three miles. The phenomena shown in Fig. 1 are susceptible of a fairly exact discussion.

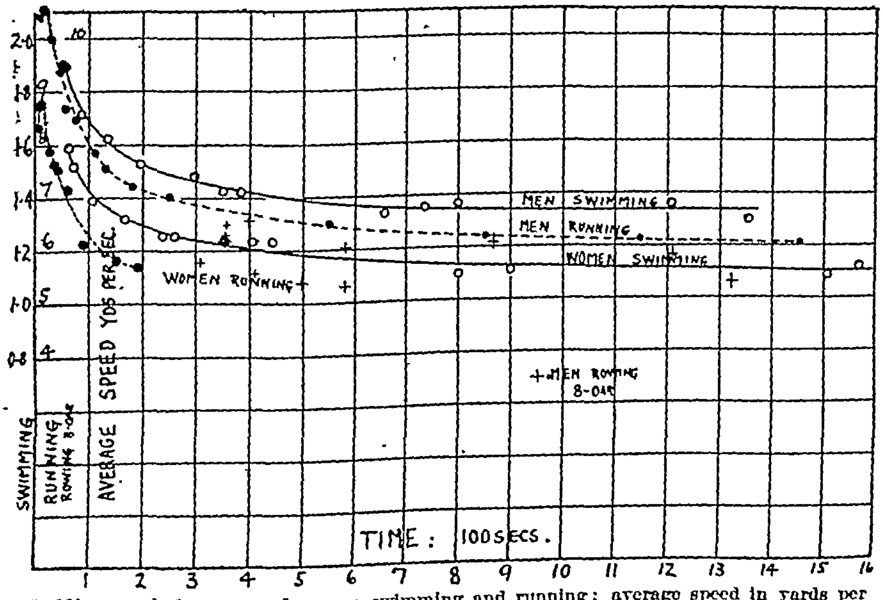
OXYGEN INTAKE, OXYGEN REQUIREMENT, AND OXYGEN DEBT.

In recent papers my colleagues and I have tried to emphasise the importance of a clear distinction between the oxygen intake and the oxygen requirement of any given type and speed of muscular effort. When exercise commences, the oxygen intake rises from a low value characteristic of rest to a high value characteristic of the effort undertaken. This rise occupies a period of about two minutes; it is nearly complete in 90 seconds. The oxygen used by the body is a measure of the amount of energy expended. One litre of oxygen consumed means about five calories of energy liberated, enough to warm 5 litres of water one degree Centigrade—expressed in mechanical energy, enough to raise about one ton seven feet into the air. It has been established, however, that the oxygen need not necessarily be used during the exertion itself. The muscles have a mechanism, depending upon the formation of lactic acid in them, by which a large amount of the oxidation may be put off to a time after the exercise has ended. The recovery process, so called, is a sign of this delayed oxidation; it is just as important to the muscle as recharging to an electrical accumulator. The degree, however, to which the body is able to run into debt for oxygen, to carry on not on present but on future supplies, is limited. When an oxygen debt of about 15 litres has been incurred the body becomes incapable of further effort; it is completely fatigued. In anything but the shortest races our record-breaking athlete should finish with something near a maximum oxygen debt, otherwise he has not employed all his available power, he has not done himself full justice. The maximum effort, therefore, which he can exert over a given interval depends upon the amount of energy available for him, upon (*a*) his maximum oxygen intake (that is, his income), and (*b*) his maximum oxygen debt (that is, the degree to which he is able to overdraw his account). These maxima are fairly well established for the case of athletic men of average size—about 4 litres per minute for the one, about 15 litres for the other.

It is possible for a man to make an effort far in excess of any contemporary supply of oxygen. This effort will require oxygen afterwards, and the total oxygen needed per minute to maintain the exercise can be measured. It is what we call the "oxygen requirement" characteristic of the effort involved. Now experiments have shown that the oxygen requirement varies very largely with the speed; it increases far more rapidly than the speed, more like the second or third power of the speed, so that high speeds and intense efforts are very wasteful. These facts enable us approximately to deduce the general form of Fig. 1.

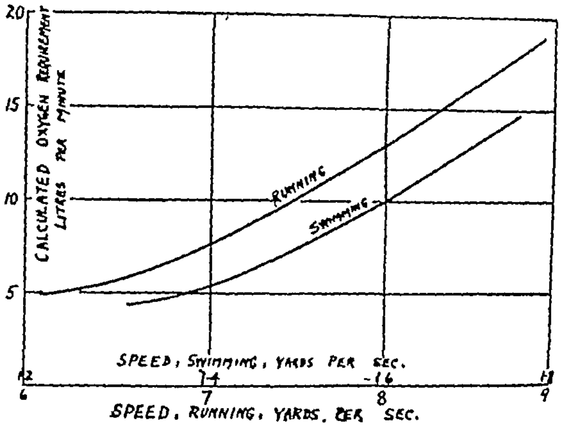
Imagine an athlete with a maximum oxygen intake of 4 litres per minute,[1] capable of running until his maximum oxygen debt has been incurred of 15 litres. If he runs for 15 minutes the total oxygen available during the exercise and in arrears is 15×4+15=75 litres; an effort can be made requiring 5 litres of oxygen per minute. Imagine, however, that he exhausts himself not in 15 but in 5 minutes; the total oxygen available during or in arrears is 5×4+15=35 litres. He may exert himself more violently, therefore, with an effort equivalent now to 7 litres per minute. Imagine next that he runs himself to exhaustion in 2 minutes: 4×2+15—i.e., 23 litres of oxygen are available, 11·5 per minute; a correspondingly greater effort can be made. By such calculations it is possible from Fig. 1 to deduce a relation between oxygen requirement and speed. Taking the case of a man swimming, the result is shown in Fig. 2 on the assumption of a maximum oxygen debt of 15 litres, a maximum oxygen intake of 3·5 litres per minute, and the supposition that at the end of the race the performer *is completely exhausted.* A similar calculated curve is given for the case of running, on the hypothesis of a maximum oxygen debt of 15 litres and a maximum oxygen intake of 4 litres per minute. There can be little doubt that the factors here described are the chief agents in determining the form of the curves given in Fig. 1.

FIG. 1.



World's records for men and women swimming and running; average speed in yards per second against time in seconds. *Note.*—The scale for swimming is five times as great as for running. The observations for men rowing an eight-oar boat are on the same scale as running and are referred to later in the text.

FIG. 2.



Oxygen requirement, running and swimming, of record-breaking athletes, calculated from curves of Fig. 1, on the assumption that at the end of a race the performer is completely exhausted, having attained his maximum oxygen debt. Maximum oxygen debt assumed = 15 litres for both. Maximum oxygen intake assumed: For running = 4 litres per minute; swimming = 3·5 litres per minute. Method of calculation described in the text.

LIMITS OF THE ARGUMENT.

It is obvious that we must not pursue the argument too far. A man cannot exhaust himself completely in a 100 or a 200 yards race; even 300 yards is not sufficient to cause an extreme degree of exhaustion, though a quarter-mile, in the case of a first-class sprinter, is enough, or almost enough, to produce complete inability to make any immediate further effort. We have found an oxygen debt of 10 litres even after a quarter-mile in 55 seconds. It is obvious, therefore, that we cannot pursue our argument below times of about 50 seconds, that the maximum speed is limited by quite other factors than the amount of energy available. It is not possible in any way to release energy explosively for very short intervals of effort; other factors determine the maximum speed, factors mechanical and nervous. Neither can the argument be applied to races, where—as we shall see below—other types of exhaustion set in.

---

[1] Assumed, for the sake of simplicity in calculation, to commence as soon as the race begins. For a more accurate calculation the gradual rise of the oxygen intake at the beginning of exercise can be taken into account.

COMPARISON OF MEN AND WOMEN: SWIMMING AND RUNNING.

There are certain characteristics of these curves which are of interest. In the first place those for men and women are almost precisely similar. For a given time of swimming the maximum speed for a woman appears throughout the curves to be almost exactly 84 to 85 per cent. of that for a man. The curve relating oxygen requirement to speed, in the case of swimming, is not known from experiment, nor are the maximum oxygen debts and the maximum oxygen intakes known for women with any certainty. It would be very interesting to determine them were volunteers forthcoming. If we assume what is roughly true, that the energy expenditure rises approximately as the square of the speed, we may conclude that a woman swimming is able to exert, per kilogramme of body-weight, about 72 per cent. of the power expended by a man. Women are well adapted to swimming; their skill in swimming is presumably just as great as that of men; the difference in the maximum speed for any given time can be a matter only of the amount of power available.

In running, the same type of comparison may be made, though here not over the same range of times. For anything but the shortest races the maximum speed of a woman is almost precisely 79 per cent. of that of a man running for the same time. For very short times, 5 to 10 seconds, the ratio is greater—namely, 84 per cent. Here, again, there would seem little reason to attribute the difference of speed, at any rate for the longer races, to anything but a difference in the maximum amount of power expendible over the period in question. Assuming again, as an approximate means of calculation, that the energy used per minute varies as the square of the speed, we see that a woman running is able to liberate in a given time only about 62 per cent. of the energy expendible by a man of the same weight. It is probable that this ratio between men and women, as determined by swimming and by running respectively, is really the same in either case, and that the apparent difference depends upon an inexactness in the simple laws we have assumed for the variation of energy expended with speed. It would seem fair to take the mean of these two values, 67 per cent.—that is, about two-thirds—as the ratio of the amount of energy expendible by a woman in a given time as compared with that by a man of the same weight. It would be of great interest—and quite simple—to test this deduction by direct experiment on women athletes.

MEN AND WOMEN JUMPING.

A further interesting comparison between men and women may be found in the records of high jumps and long jumps. The world's record long jump for a man is 25 5 feet, for a woman 16 9 feet. The high jump records are respectively 6 61 feet and 5 feet. At first sight, when compared with running, these records for women seem extraordinarily poor; the high jump is only 75 5 per cent., the long jump only 66 per cent., of that for men. Such a conclusion, however, rests upon a misunderstanding, almost like that which makes many people believe that if a man could jump as well as a flea he could easily clear the top of St. Paul's Cathedral. It is a matter only of elementary mechanics to show, on the assumption that a woman can project herself vertically with a velocity proportional to that with which she can project herself horizontally, the constant of the proportion being the same as for the case of a man, that both the high jump and the long jump in the two sexes should be in the ratio *not of the velocities but of the squares of the velocities*. The maximum range and the maximum height of a projectile vary as the square of the velocity of projection. Thus it is right to compare, for men and women, not the height of the high jump or the distance of the long jump, but the square roots of these quantities, if we wish to study their relative performance in jumping as compared with running. This being so, we find that the high jump of a woman, as measured by its square root, is 87 per cent. of that of a man[*]; the long jump, measured in a similar way, is 81·5 per cent. These compare closely with their relative performances for very short times of running, where a woman, as shown above, can run 84 per cent. as fast as a man. It is amusing to find simple mechanics explaining such apparent differences between the sexes.

SKILL.

Some people are much more skilled than others. To a large degree, of course, the skill and grace associated with athletic prowess is natural and inborn; to a large degree, however, it can be produced by training and breeding. All the movements required in the violent forms of muscular exertion here discussed are rapid ones, far too rapid to be directly and continuously subject to the conscious intelligence; they are largely, indeed mainly, reflex, set going by the will but maintained by the interplay of proprioceptive nervous system and motor apparatus. The nature of muscular skill cannot be discussed here; possibly, however, above all other factors it is the foundation of athletic prowess. Such skill has a physiological basis as it has a psychological aspect. It is a fit subject for discussion alike by physiologists, psychologists, students of physical training, athletes, masters, and workmen. The further study of skill is likely to be most fruitful in many branches of human endeavour. Given incorrect adjustment due to lack of skill, given imperfect timing of the several parts of the mechanism, given unnecessary movement and vibration, the whole system will be inefficient. Fundamentally the teaching of athletics for anything but the shortest distances consists in training the performer to carry out the same movements at a given speed for a smaller expenditure of energy.

BICYCLING AND HORSE-RUNNING.

Not all forms of muscular exertion are so violent, involve so great an expenditure of energy, when carried out at the highest speed, as running and swimming. In Fig. 3 are two examples of this fact, horse-running and bicycling. For horse-running a long succession of records on American horses are plotted on the topmost curve; below are the records of men bicycling, the unpaced professional records, made not in a race but against time. Most bicycle races are useless for our purpose. The competitors proceed in groups, trying one to ride behind the other to avoid wind resistance, and the speed may be absurdly low. Paced records are of little value because the efficiency of the wind-screen provided by the pacing apparatus is not standardised. These professional records, however, made unpaced, simply with the intention of breaking the record, are probably reliable, and they form a reasonably smooth curve. Plotted on the same diagram for comparison is a curve to represent a man running, a replica of that of Fig. 1. The first two curves are on twice the scale of the third, since a running horse and a bicycling man can go about twice the speed of a running man. It is obvious at once that neither of these two curves falls anything like so rapidly as does that of a running man; fatigue does not so soon set in; the amount of energy expended at the highest speed must be much less than in a running man. This conclusion, indeed, is obvious to anyone who has tried to ride a bicycle fast. It is impossible to exhaust oneself rapidly on a bicycle; the movements are too slow, they involve too little of the musculature of the body; it would require some minutes to produce by bicycling a state of exhaustion easily attainable within a minute by running. The curve for horse-running is almost parallel to that for bicycling; presumably, therefore, the movements of a horse are so arranged that the extreme violence of effort possible in a human "sprinter" is unattainable. Possibly the movements are too infrequent, or the qualities of the horse's muscles are so different, that the kind of fatigue rapidly attainable in man is not possible in the horse; possibly the horse will not "run himself out" so completely as a man.

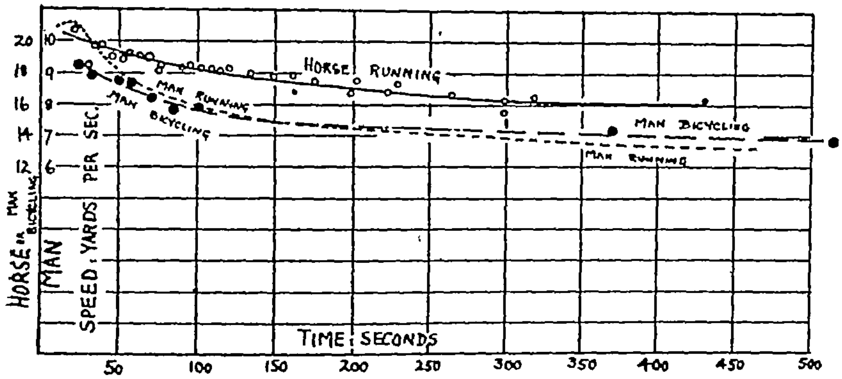
---

[*] It would really be fairer to compare the heights jumped, less the initial heights of the centres of gravity, say 3 1 feet and 2·8 feet respectively. This gives 2·2/3 51 = 0·63 as the ratio of the heights, of which the square root is 0·79, a close agreement with the long jump.

BICYCLE ERGOMETERS.

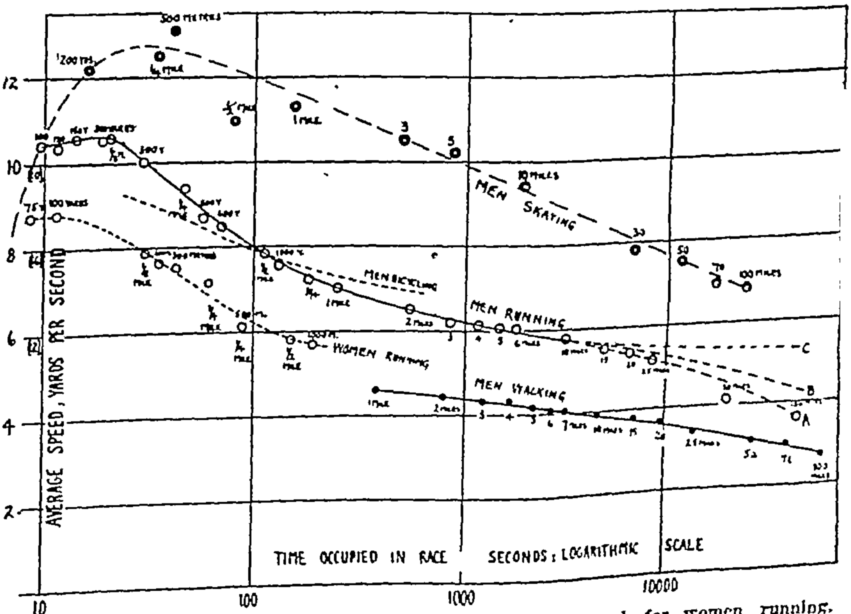
The curves of Fig. 3 are of interest in connexion with the numberless experiments which have been made with bicycle ergometers. Nearly all the laboratory observations on man, in connexion with muscular exercise, have been made with that implement. It has been obvious to my colleagues and myself during the last few years that the types of exercise chiefly adopted by us, running and standing-running, are more exhausting and require a far greater expenditure of energy than those employing the bicycle ergometer. In rowing and in pedalling a bicycle it may not be possible to attain respiratory quotients of 2 or more during or shortly after exercise. After running, or standing-running, however, very high values are attained, due to the fact that these latter forms of exercise, at the highest speeds, are so very much more energetic than the slower movements of rowing or bicycling. It is speed and frequency of movement which determine the degree of exhaustion produced by it. To exert a powerful force in a moderate rhythm is not anything like so tiring as to exert a much smaller force in a frequent rhythm; hence the reason for "gearing up," as in the bicycle and in the long oars of a rowing-boat.

FIG. 3.



Records for horse running and man bicycling; dotted curve for comparison, man running, taken from Fig. 1. Horizontally, time in seconds; vertically, average speed yards per second. *Note.*—The horse and the man bicycling are shown on half the scale of the man running. *The records for bicycling are the unpaced professional records against time.* The records for horses were made in America.

FIG. 4.



Records for men skating, bicycling, running, and walking, and for women running. Horizontally, logarithm of time occupied in race; vertically, average speed in yards per second. The same scale is used throughout, except for bicycling, where half the scale is employed, as shown in square brackets. The curve for men running appears to be somewhat doubtful beyond 10 or 15 miles, and three alternative curves are shown by broken lines.

[After a further illustration from English horse racing the lecturer proceeded to a consideration of the last diagram, Fig. 4.]

THE LOGARITHMIC GRAPH.

Where average speed in a race is plotted against the logarithm of the time occupied in it, the logarithm being employed, as stated above, for the purpose of including all records from 75 yards to 100 miles in the same picture. That people think, to some degree, in logarithms, although unconsciously, is shown by the fact that the records which men have thought it worth while to make are distributed approximately uniformly over the picture from left to right. Fig. 4 presents the data of athletics perhaps more clearly than any other. The initial rise of the curve for men running, which is due to starting inertia, is very obvious. The rapid fall beyond 220 yards is clearly seen. It is obvious that the 100 and the 220 yards (⅛ mile) records are better than those lying in their neighbourhood, that the quarter-mile record is extremely good, the 500 yards record very bad, by comparison with its neighbours. This diagram should enable any enterprising and scientific athlete to select the records most easy to break. Let him try those for 120 yards, for 500 yards, for three-quarter mile, for three miles, but not for 200 yards, quarter mile, one mile, and six miles.

LONG-DISTANCE RECORDS.

In Fig. 1 we saw that the speed fell to what seemed to be practically a constant level towards the right of the diagram; this fall represents the initial factor in fatigue. On the logarithmic scale, however, where the longer times are compressed together, the curve continues to fall throughout its length. This later fall is due to factors quite different from those discussed above. Consideration merely of oxygen intake and oxygen debt will not suffice to explain the continued fall of the curve. Actually the curve beyond 10 miles seems to some degree doubtful. Apparently the same extent of effort has not been lavished on the longer records. The greatest athletes have confined themselves to distances not greater than 10 miles. The curve A drawn through all the points has a suspicious downward bend in it, which suggests that if Alfred Shrubb or Nurmi had tried to break the longer records they would have done so very effectively. Possibly the true curve lies more like the continuation C; possibly it may be intermediate as shown at B. It would seem doubtful, indeed, whether the running curve and the walking curve are really to meet at about 150 miles. The most probable continuation of the running curve would seem to be somewhere between the lines B and C.

The continued fall in the curve, as the effort is prolonged, is probably due to the second and third types of fatigue which we discussed above, either to the exhaustion of the material of the muscle, or to the incidental disturbances which may make a man stop before his muscular system has reached its limit. A man of average size running in a race must expend about 300 g. of glycogen per hour; perhaps a half of this may be replaced by its equivalent of fat. After a very few hours, therefore, the whole glycogen supply of his body will be exhausted. The body, however, does not readily use fat alone as a source of energy; disturbances may arise in the metabolism; it will be necessary to feed a man with carbohydrate as the effort continues. Such feeding will be followed by digestion; disturbances of digestion may occur—other reactions may ensue. For very long distances the case is far more complex than for the shorter ones, and although, no doubt, the physiological principles can be ascertained, we do not know enough about them yet to be able further to analyse the curves.

Women's Running Records.

The women's curve, as far as it goes, is very similar to the men's. Some records again are better than others. An enterprising woman athlete who wants to break a record should avoid the 300 metres; she would be well advised to try the 500 metres. It would be very interesting to have an intermediate point between 100 and 200 yards.

Bicycling and Walking.

As before, the curve for men bicycling, which is drawn on twice the scale vertically of the running curves, is far less steep than they are. The conclusion from this was emphasised above. The walking curve is interesting—it is approximately straight. Physiologically speaking, there is not much interest in the shortest walking races, since here walking is artificial and extremely laborious; running at a considerably higher speed is much more easy. For longer distances, however, say from 10 miles onwards, we have probably in walking the most reliable data available for long-continued muscular effort. If we wish to study the exhaustion produced by exercise of long duration, walking-men may well provide the best subjects for our experiments.

Skating.

There remains the top curve of all, that for men skating. The initial rise of the curve, due to starting inertia, is very obvious. The fall of the curve beyond the maximum is nowhere near so rapid as for the case of running. Clearly in skating a man is not able to exert himself with the degree of ardour that is possible in the more primitive exercise of running. Skill and restraint are necessary, as they are in bicycling. There are limits to the output. Moreover, the effort can be continued for a long time at comparatively high speeds. It is interesting to note that a man can skate 100 miles at almost the same speed as another man can run one mile. The curve falls uniformly throughout as does the walking curve. Clearly the phenomena of gradual exhaustion could be well investigated in the case of skating. Here, again, it is obvious which records the aspiring athlete should attempt to break.

Rowing.

There are only a few records available, and those lying between rather narrow limits, for the case of rowing. Taking the case of an eight-oar boat, I have been able to obtain very few reliable data. Kennelly gives records of crews rowing, for times from 305 to 1210 seconds. Yandell Henderson, in the *American Journal of Physiology* (vol. lxxii., p. 264, 1925), gives five observations made upon the Yale crew of 1924. In addition there are records for the Henley course; these, however, are usually contaminated by the speed of the water. The most reliable of the data have been plotted in Fig. 1 on the same scale as the running, on five times the scale of the swimming. The observed points, shown by crosses, are somewhat scattered. As far as they go, a mean curve through them would lie practically along the curve for women swimming, but, of course, on five times the scale. The interesting part of the curve to the left is lacking; it is obviously impossible to make observations on an eight-oar boat for periods of 20 seconds, starting inertia is too great and no result of any value could be obtained. It would, however, be of interest to obtain data as far back as possible; certainly the records of crews rowing in still water for a minute and above should be ascertainable, and they would help to fit rowing into the scheme outlined by the other types of muscular effort.

Work and Stroke Frequency in Rowing.

In rowing the movements are slow; in an eight-oar boat, from 30 to 40 strokes per minute. According to observations by Lupton and myself the maximum efficiency of human muscular movement is obtained at speeds of about one maximal movement per second. In rowing, experience and tradition alike suggest that such a speed is about the optimum. In an eight-oar boat the recovery takes almost as long as the stroke, both occupying about one second. It is of interest how practical experience has gradually evolved a speed of movement which is almost exactly what a physiologist might have predicted as the most efficient. At a stroke of about 32 per minute the mechanical efficiency is apparently near its maximum. An enormous amount of work has to be done in propelling a boat at speeds like 10 to 12 miles per hour. According to Henderson, each member of the crew of an eight-oar boat must exert about 0·6 of a horse-power. Clearly if this enormous amount of external work is to be done it must be accomplished by working under efficient conditions. Those conditions necessitate a stroke of a particular frequency; only when the race is very short is it permissible, in order to obtain a greater output, to work less efficiently by adopting a more rapid stroke. The stroke may rise to 40 per minute for a short distance; in such an effort the oxygen debt is accumulating rapidly and exhaustion will soon set in. The amount of work, moreover, will not be proportionately greater, probably only slightly greater, than at the lower frequency. The conditions which determine the speed of movement, the "viscous-elastic" properties of muscle, are what ultimately decide the length of the oars and the speed of movement in a racing-boat. It is interesting to find—as, of course, was really obvious—how closely athletics is mixed with physiology.

Wastefulness of High Speeds.

This last discussion leads us to the question of what determines the great wastefulness of the higher speeds. Why does a speed of 280 steps per minute require 24 litres of oxygen per minute, while a speed of 240 steps per minute requires only eight litres of oxygen? The answer depends upon the variation of external work with speed of muscular movement. In a series of recent papers it has been shown that in a maximal muscular movement the external work decreases in a linear manner as the speed of shortening increases. At sufficiently high speeds of shortening no external work at all can be performed. In most of these athletic exercises, apart from the case of rowing, a large proportion of the mechanical work is used in overcoming the viscous resistance of the muscles themselves. At high speeds of running only a small fraction of the mechanical energy of the muscles is available to propel the body once the initial inertia has been overcome. The speed of shortening is so rapid that little external work can be done. The work is absorbed by internal friction, or by those molecular changes which, when the muscle is shortening rapidly, cause its tension to fall off. When working against an external resistance, as in rowing, there is an optimum speed. If an effort is to be long continued it must be made at a speed not far from the optimum. When, however, the whole of the resistance to movement is internal, as in running, there is no optimum speed; *the expense of the movement increases continually as the speed goes up*; the faster we move, the greater relatively the price. Our footsteps are dogged by the viscous-elastic properties of muscle, which prevent us from moving too fast, which save us from breaking *ourselves while we are attempting to break a record.*

Uniform Speed is the Optimum.

The amount of energy required per minute to run or to swim, or, indeed, to propel oneself in any way, increases more rapidly than the speed—in the cases which have been investigated, approximately as the square of the speed. This mathematical relation is not exact. From the variation of energy output as the square of the speed, we can immediately deduce that the most efficient way in which to run a race is that of a uniform speed throughout. Imagine that a man runs a mile race in 4 minutes 30 seconds at a uniform speed of 6·52 yards per second. His energy expenditure is proportional to 4½ times 6·52 squared—that is, 191·3 expressed in some arbitrary units. Imagine now that he runs it at two speeds, 6 and 7 yards per second, 780 yards at the lower, 980 at the upper speed. The total time is the same; the energy expended, however, is slightly greater, 192·3 instead of 191·3. This small variation of speed in the race has produced no serious increase in the energy expenditure. Let us imagine, however, that one portion of the race, 665 yards, is run at 5 yards per second, while another portion, 1096 yards, is run at 8 yards per second. The total time occupied in the race is still 4 minutes 30 seconds. The energy expended, however, is greater—namely, 201·5 units. Even this, however, is not a very large increase; by running about half the time at 8 yards and half the time at 5 yards per second, the energy expended has been increased only about 5 per cent., as compared with that required for running at a uniform speed of 6·5 yards per second throughout. Although, therefore, theoretically speaking, the optimum fashion in which to run a race is that of uniform velocity throughout, comparatively large variations on either side of this velocity do not appreciably increase the amount of energy expended.

Possible Advantages of a Fast Start.

There may, indeed, be advantages in starting rather faster than the average speed which it is intended to maintain. The sooner the respiration and circulation are driven up to their maximum values the greater will be the amount of oxygen taken in by the body, the greater the amount expendible during the race. It is a common practice in mile races to start very fast and to settle down later to the uniform speed. This may have a physiological basis in the quickening up of circulation and respiration achieved thereby.

The Simple Mechanics of High-Jumping.

One final point may be worthy of mention—this time connected with high-jumping and long-jumping. Recently I made a series of observations, with a stop-watch reading to 0·02 seconds, of the times occupied by a number of high-jumpers from the moment they left the ground to the moment they reached the ground again. With men jumping about 5 feet the time averaged about 0·80 second. Calculating from the formula

$$S = \tfrac{1}{2}gt^2,$$

where t is half the total time of flight, the distance through which the centre of gravity of the body was raised must have been about 2·5 feet. The men competing must have had an original height of their centre of gravity of about 2·7 feet. Thus, in the high-jump, their centres of gravity went about 5·2 feet high into the air. They cleared a height of 5 feet; they just managed to wriggle their centres over the bar. Now, paradoxical as it may seem, it is possible for an object to pass over a bar while its centre of gravity passes beneath; every particle in the object may go over the bar and yet the whole time its centre of gravity may be below. A rope running over a pulley and falling the other side is an obvious example. It is conceivable that by suitable contortions the more accomplished high-jumpers may clear the bar without getting their centres of gravity above or appreciably above it. Let us calculate, however, on the assumption that the centre of gravity of a jumper just clears the bar. The world's record high-jump is 6·61 feet, the centre of gravity of the performer being presumably about 3 feet high at rest. He raises it therefore 3·61 feet into the air, from which we may calculate that the whole time occupied in the jump is about 0·96 second. Seeing the amazing complexity of and the skill involved in the rapid movements and adjustments involved in a record high-jump, it is striking that all those events can occur within a time of less than one second. All the characteristics of the proprioceptive system must be evoked in their highest degree in carrying out such a skilled, rapid, and yet violent movement.

Long-Jumping.

It is well known to athletes that success in long-jumping consists in learning to jump high. It is not, of course, the case that a record long-jumper performs at the same moment a record high-jump. He must, however, cover a very considerable height. The world's record long-jump is 25·48 feet. With the check provided by the vertical impulse in the last step we cannot well imagine the horizontal velocity to be greater, at this moment, than that of 100 yards completed in 10 seconds—that is, than 30 feet per second. Let us assume this value. Then the performer remains in the air for $\frac{25{\cdot}48}{30}$, that is, 0·85 second. Hence we may calculate that the vertical distance covered is about 2·9 feet. Assuming the centre of gravity of the subject to have been originally 3 feet high, this means that it must have reached a height 5·9 feet in the air, enough, in a high-jump, to enable its owner to clear 5·9 feet. It is interesting to find that the simple laws of mechanics emphasise so strongly the precepts of the athletic trainer. Not only must one jump high if one wishes to break a long-jump record, but one must bring one's centre of gravity nearly 6 feet high into the air; for one must project oneself vertically, so that one may remain for 0·85 second above the ground.

Conclusion.

The practice of athletics is both a science and an art, and, just as art and science are the most potent ties tending to draw men together in a world of industrial competition, so sport and athletics, by urging men to friendly rivalry, may help to avert the bitterness resulting from less peaceful struggles. If, therefore, physiology can aid in the development of athletics as a science and an art, I think it will deserve well of mankind. As in all these things, however, the reward will be reciprocal. Obviously in the data of athletic records we have a store of information available for physiological study. Apart from its usefulness, however, I would urge that the study is amusing. Most people are interested, at any rate in England and America, in some type of sport. If they can be made to find it more interesting, as I have found it, by a scientific contemplation of the things which every sportsman knows, then that extra interest is its own defence.

SOME
Practical Considerations
IN THE CONSERVATIVE TREATMENT OF FRACTURES OF THE PELVIS AND LOWER EXTREMITY.[*]

A Course of Four Lectures delivered for the University of London at St. Bartholomew's Hospital

BY SIR WILLIAM I. DE COURCY WHEELER,
M.D. DUB., F.R.C.S. IREL.,

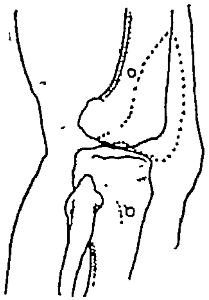
LECTURE III.[*]

FRACTURES ABOUT THE KNEE-JOINT.

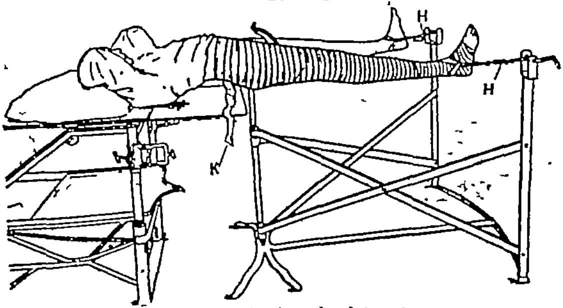
FRACTURES of the lower end of the femur into the knee-joint are not uncommon. They resemble closely articular fractures of the lower end of the humerus. The condyles may be comminuted, or there may be simple fractures through either condyle. Replacement of the fragments usually takes place under extension. A Thomas knee-splint, applied in the classical fashion, is the best apparatus for the purpose. Traction on the tibia pulls the condyles into correct position by the tension of the lateral and crucial ligaments. By separating the joint surfaces during treatment adhesions are prevented and early movements facilitated. Stretching of the ligaments during treatment *does not* produce any permanent disability.

FIG. 1.



Positions for transfixion pins.
(Hey Groves.)

FIG. 1A.



"Gate" extension apparatus (reproduced from THE LANCET, August 22nd, 1925, p. 364)

It is best for the surgeon to manipulate the condyles with his hands while the assistant is applying extension in these cases. "So long as the tibia is not allowed to bump up against them," says Sir Robert Jones, "they will not be again displaced. If immediate reduction does not occur, quite often after a 12 hours' extension on the Thomas splint the displaced fragment will find its proper position." Fractures of the tuberosities of the tibia and T-shaped fractures into the joint are dealt with in the same way. About six weeks after these injuries the patient may move about on a calliper splint.

Epiphyseal Separation.

The lower fragment is usually displaced forwards, and the ragged end of the upper fragment is pushed backwards in relation to the popliteal vessels. The injury is sometimes compound, and in many recorded cases amputation has become necessary.

Reduction is accomplished by strong flexion until the heel touches the buttock, combined with traction on the tibia and direct manipulation. In order to save the limb open reduction may become necessary. Union usually takes place by bone, and is followed by some shortening and interference with growth. The injury should be treated in full flexion, as in similar fractures involving the elbow-joint. In the latter case the triceps, with the limb in flexion, provides a nicely grooved natural splint for the prevention of backward displacement and, in the case of the knee-joint, the quadriceps extensor when the limb is flexed forms a naturally moulded anterior splint which admirably controls the fragments and prevents forward displacement.

In epiphyseal separation of the lower end of the femur the limb, after reduction, should be carefully watched lest anything in the nature of tight bandaging or tight compression produces swelling of the feet. The condition of the circulation in children, when firm fixation is required, needs strict attention. "Look well to the blood-supply of the limb below the point of injury, more especially in *all* fractures of the lower extremity," is the advice of Bryant and Buck in the "American Practice of Surgery" (Vol. III.).

Traction by Pins, Callipers, and Stirrups.

Before dealing with the treatment of mal-union and non-union after fracture of the femur, it is necessary to refer to the question of extension applied by means of metal appliances attached to, or passed through, the bone. These appliances consist of various pins, callipers, and stirrups; each surgeon has his preference for one or the other. The transfixion pin is the only one I myself employ, and quite often it takes the form of a long nail, such as is used for the temporary fixation of joints after excision. The skin is pulled upwards towards the hip to prevent subsequent traction pressure on the skin below the pin. The point of election for transfixion is just above the condyles at their junction with the shaft. If a pin is driven through the compact tissue of the femur at the point indicated, it can be left in place without inconvenience or pain for from six to eight weeks. A handle improvised from wire is attached to the pin. In the cases I have treated I have passed the pin through *the tibia*, not the femur. It is passed through the shaft of the tibia just behind and below the tubercle. In this position the bone is thick and hard, and the pin can be left in position for two or three months (Fig 1).

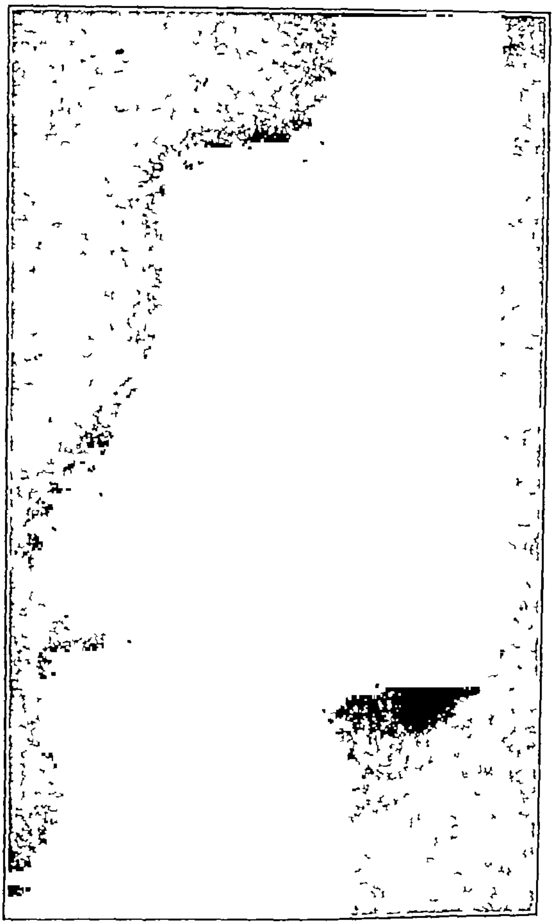
In the case of fractures of both bones of the leg, when this form of extension becomes *necessary*, the pin is passed by some surgeons above, but in the line of, the malleoli, well clear of the ankle-joint, about three finger breadths above the tip of the external malleolus. Personally, I prefer transfixion of the os calcis. The pin is passed one inch below and behind the tip of the external malleolus, downwards and inwards in such a way that traction produces inversion of the foot.

---

[*] Lectures I and II. appeared in THE LANCET of August 15th and 22nd respectively, and Lecture IV. will appear in a subsequent issue.

Full information on this subject is to be found in the excellent work on "Modern Methods of Treating Fractures," by Hey Groves.

FIG. 2.



Mal-union of femur (lower third) three months after the injury. 3½ inches shortening. (Lateral view.)

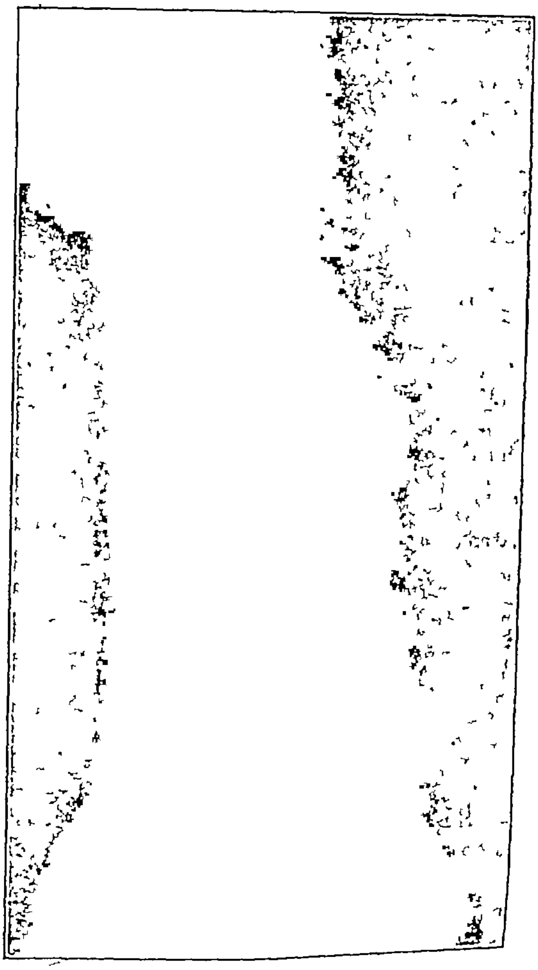
MAL-UNION AND NON-UNION.

Mal-union and non-union are due, probably in 90 per cent. of cases, to mal-treatment. They are a reproach to surgery, and can always be avoided. It is no use blaming constitutional disease, or the interposition of soft tissues between the fragments for these unpleasant sequelæ. The primary treatment is practically always at fault, and is thus the main causative factor. The primary treatment may be good, but if the patient is allowed to bear weight too early, yielding of the callus with angulation and overlapping will take place.

The time of strong union in a fractured bone varies in almost every case, and the length of time given for solid union in the text-books never errs on the safe side. In a small percentage of cases twice as much time is required as in a typical case. To allow walking without a calliper splint in the case of a fractured femur before three months have elapsed is asking for trouble, and under certain conditions a much longer period is required. Cases of non-union are often unrecognised cases of delayed union, and the dividing line between the two is very obscure. For some reason or another union is slow, and at the end of five or six weeks the surgeon becomes anxious, and moves the fragments one upon the other; in another four or five days he tries again, and, by a continuation of this process, it is made impossible for the slowly-forming permanent callus to complete the union.

The treatment of definitely ununited fractures must, of course, be operative, but the surgeon should feel morally certain that it is a case of non-union, and not delayed union, before operation is undertaken. In this matter I have tried to follow the teaching of Sir Robert Jones. His usual practice is simply to begin again and wait, and to try and induce osteogenetic activity by Thomas's so-called "percussion and dam" method. After hammering the whole region of the fracture with a padded or indiarubber mallet, a tight elastic band is applied both above and below the fracture at a distance of several inches. The limb between the tubes swells to much more than its normal girth, expanding all the capillaries and lymph paths in the fibrous tissue, and allowing a new process of repair to start. The indolent callus may thus be transformed into an osteogenetic factory. The rubber tubes can be worn only for about 20 minutes each day at first; afterwards they can be borne for several hours at a time. They should be kept tied sufficiently tightly to produce considerable swelling and stasis. Local congestion between two tubes is much more effective than when one proximal tube is used. There is no doubt that non-operative treatment should be tried in cases of apparent non-union, in the hope that they are cases of delayed union. Only when efficient

FIG. 3.



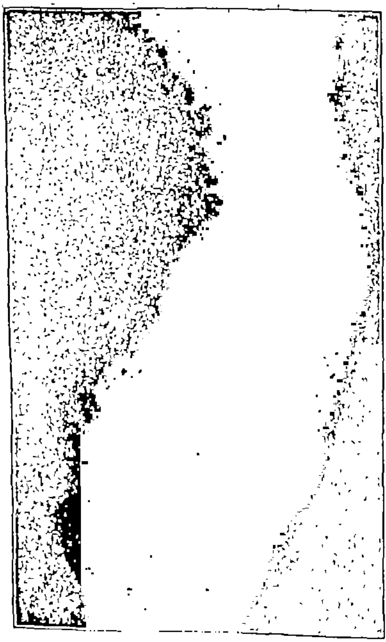
Position after two extensions on "gate" apparatus and traction from a pin through the tibia. The injured leg is now longer than normal.

conservative treatment fails should the case be condemned as one of non-union. Bone-grafting and reconstruction operations are then undertaken.

It is surprising what good results can be obtained in cases of mal-union of the femoral shaft with 3 in. or 4 in. shortening. Even after three or four months it is not difficult to re-break the fracture manually. In most of the cases I have seen the knee was stiffened by the previous treatment, and the mal-union could be broken down by forcible bending of the knee over the edge of the table. The worse the position of the bones, the less firm will be the exuberant callus. In old-standing cases of mal-union it may not be possible to re-fracture a bone, and the simplest method to employ is an oblique osteotomy through the callus between the original fragments of the shaft.

When the mal-united fracture has been re-broken and thoroughly freed manually, forcible extension by some means or another will reduce the shortening at one sitting by from 2 in. to 3 in. It has been my practice, after re-fracturing the bone, to forcibly stretch the limb for a few minutes on the gate apparatus (*Fig.* 1A), and while still stretched to apply a Thomas splint with fixed tape extension. While the limb is stretching on "the gates," and before the tapes are tied to the end of the Thomas splint, a nail or pin is passed through the tibia, as recommended by Hey Groves, just behind and below the tubercle. When the patient is back in bed a pulley is connected by a strong wire loop to the nail. When the patient returns to the ward a cord is tied to the end of the Balkan frame, is brought round this pulley, and passed over a pulley at the end of the bed; 20 lb. weight is at first employed, but with this arrangement of pulleys, apart from friction, the resultant weight is equivalent to 40 lb. This pin or calliper traction takes the place of the fixed extension. If, in a week's time, the shortening has not been completely corrected, the patient is brought to the theatre, anæsthetised, and the limb again stretched on the gate apparatus. It is seldom necessary to repeat the process more than once, and quite often the treatment will result—if not carefully watched—in the leg becoming too long (Figs. 2 and 3).

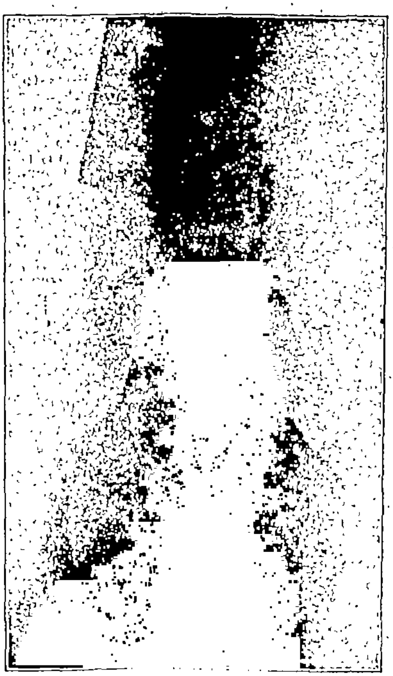
FIG. 4.



Late or secondary displacement. After six weeks the splints were removed in order to fit a calliper with the result shown. The patient never left bed.

I have had in my Private Hospital during the last year a man, aged 70, whom Mr. Hey Groves kindly saw with me. He fractured the lower third of his femur when in a state of alcoholic exuberance, and did not think seriously of treatment for three months after the accident. The lower fragment was in the usual position behind; the upper fragment impaled the soft tissues at the outer side of the patella like a bayonet, and there was over 3½ in. shortening. Three months had elapsed, but there was no difficulty in breaking down the fracture by manipulating the knee over the edge of the table. The first stretching on the gates reduced the shortening by 2 in. For a week he was treated in fixed extension in a Thomas splint. Shortening to the extent of 1½ in. persisted, and further forcible extension on the gates was employed. The shortening was this time completely reduced. With the assistance of Mr. Hey Groves, a pin was passed through the strong portion of the tibia in the region of the tubercle, and 40 lb. extension applied when the patient returned to bed. The weights were gradually reduced after the first fortnight to about 15 lb. Two months later the injured limb was found longer than the other.

FIG. 5.

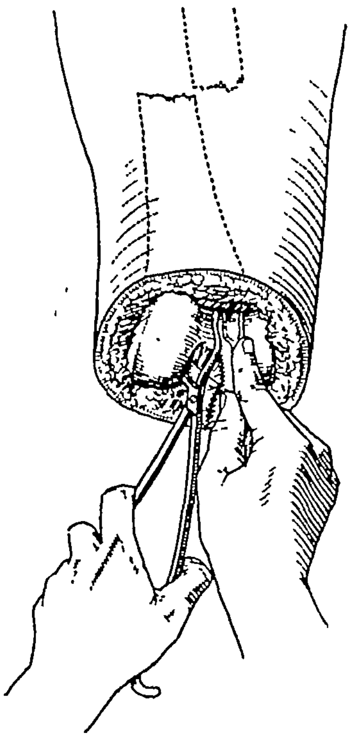


Same case as Fig. 4 showing femur ½ inch too long after "gate" extension (see Fig. 1A) and pin traction.

Late or Secondary Displacement.

With calliper or pin extension, over-lengthening of the bones may be produced more readily than when other methods are employed. Care must be taken lest deformity recur after two or three months, owing to the plastic condition of the intervening callus, even though the patient is still kept in bed. There should be no interval between the removal of the extension and the application of a calliper splint. The latter should be worn both night and day for a considerable period. In the case just mentioned, the full length obtained and the good alignment were partially lost by allowing the patient to lie for a couple of days after two months without the extension. The final result was functionally good, with about ¾ in. shortening.

FIG. 6.



Sleeve amputation. The limb is removed by circular amputation and the bone shelled out in the manner shown.

I had experience of another case, in which a transverse osteotomy was performed in the lower third in order to correct outward rotation of the foot following gunshot injury to the hip (Figs. 4 and 5). A Thomas knee-splint was used for fixation, but was removed at the end of five or six weeks in order to fit a calliper. Before the latter was completed lateral displacement and overlapping of the fragments occurred, although the patient never left bed. This was subsequently corrected by re-breaking, stretching on the gates, and pin traction. After consolidation it was found that the leg had been lengthened by ½ in. beyond normal.

This question of late or secondary displacement requires some attention. It was new to me until recently, and I used to think of it as occurring only when patients were allowed to walk too soon without support. In both the cases to which I have alluded, the broken ends were held in good alignment, but in the first there was not close apposition, and a large gap remained to be filled up with reparative material. Such repair tissues undergo ossification in the adult very slowly, and probably at the end of six or eight weeks they are quite plastic. In a day or two the muscular tension may slowly deform the seat of fracture, so that the final result is very far short of that which was promised by X rays in the course of treatment. Hey Groves comments on this, and states that late displacement is specially liable to occur in the femur of adults.

One would hardly think it possible that an interval of a few days without apparatus, while the patient is still in bed, after six or eight weeks of extension, would lead to shortening and displacement, but that such may occur—especially where the treatment was for mal-union or where too much lengthening has been produced—is beyond doubt.

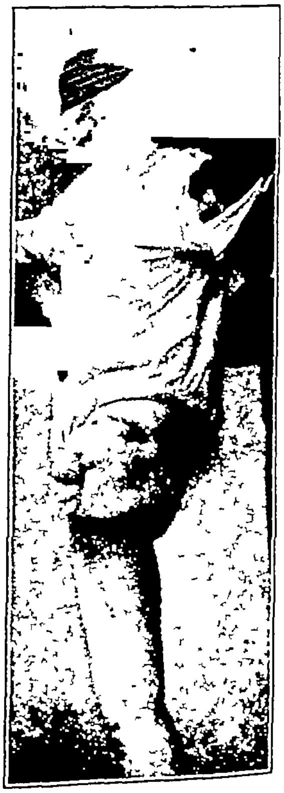
Amputation after Fracture of Femur.

Although I am dealing here with conservative treatment, I must mention that I have had four cases of fractured femur, in private practice, which ended in amputation. In three out of the four the limb was removed by a procedure I have called the "sleeve" amputation (Fig. 6). It is a modification of the discarded guillotine operation, and appears to me to be applicable to a group of cases in which orthodox methods would result in needless mutilation.

The method is designed to meet certain emergency operations with the least possible surgical risk, and with a view to the conservation of the longest possible stump. The orthodox method of obtaining healthy flaps well above the injury or disease is departed from, and the amputation is carried very much lower than most text-books would sanction.

I will quote one case by way of illustration:—

FIG 7.



Stump some years after a sleeve amputation for compound fracture of the femur in the upper third.

In 1916 a man was run over by a motor lorry and sustained a fracture about the middle of the shaft of the right femur. Ten days afterwards he was seen by me. The leg, from the foot to just below the knee, was gangrenous; the thigh was enormously swollen, red, and œdematous; the skin was mottled and vesicated, and large patches of black and purple discoloration extended over a wide area. The thigh had all the appearance of the early stages of moist gangrene which had already destroyed the leg. The œdema, vesication, and discoloration extended upward on the abdomen. A tourniquet could not be employed owing to the condition of the soft tissues, and for the same reason digital compression of the vessels was impossible.

An incision was made exposing the upper portion of the femoral artery for a length of 2 or 3 inches in order to ascertain its condition. The artery was pulsating at this level, and was held by an assistant between finger and thumb. A circular amputation was quickly performed *through* the knee-joint, just above the line of definite gangrene. The incision was carried above the margin of the patella in front, and the quadriceps extensor tendon divided. The attachments of the soft tissues to the femur were separated with knife and periosteal elevator until the lower segment could be withdrawn, like a cork from a bottle, by the rotatory movements of a heavy bone forceps. When the assistant released the femoral artery *there was no bleeding whatever at the end of the stump. At this level the vessels were thrombosed and obliterated.* The lower half of the thigh had now the appearance of the sleeve of a coat from which the hand and forearm had been removed. The sleeve was left open and lightly packed with iodoform gauze.

The man made an uninterrupted recovery, except that there was an extensive sloughing of the skin in the upper portion of the thigh. He was seen in August, 1923, seven years after operation, and was walking without pain or discomfort with his artificial leg. A scar about the size of the palm of a hand in front and above indicated where the skin sloughed and had been skin-grafted. The scar through which the femoral artery was exposed was well seen on the inner side. An X ray photograph showed irregularities about the end of the femur, and the formation of well-marked osteophytes. Owing to the adequate covering of soft tissues, these gave rise to no pain or discomfort whatever.

Fig. 7 shows the stump some years after a sleeve amputation for comminuted compound fracture of the upper third of the femur, the result of a bullet wound. Before amputation the soft tissues were riddled with discharging sinuses.

CATARACT EXTRACTION IN EGYPT.*

BY A. F. MACCALLAN, C.B.E., M.D. CAMB., F.R.C.S. ENG.,

ASSISTANT OPHTHALMIC SURGEON, WESTMINSTER HOSPITAL; ASSISTANT SURGEON, ROYAL EYE HOSPITAL; FORMERLY DIRECTOR OF THE EGYPTIAN GOVERNMENT OPHTHALMIC HOSPITALS.

IN a country such as Egypt, where trachoma is endemic and affects about 90 per cent. of the population, the preparation of cases as a preliminary to the extraction of cataract is an important matter. It is not the presence of the trachoma itself which is the danger, but the coexistence of such organisms as the pneumococcus, streptococcus, staphylococcus, Morax-Axenfeld bacillus, Koch-Weeks bacillus, and gonococcus, which has to be negatived before operation can be considered as safe.

The appropriate treatment for the particular stage of trachoma found in each case is adopted, and treatment is continued until the conjunctival secretion becomes innocuous.

Preparation of the Patient for Operation.

It is sometimes exceedingly difficult to get rid of dangerous organisms from an eye preparatory to operation. Where this is not possible after treatment as an in-patient for a fortnight, and where the conjunctiva is fairly smooth, we proceed with the operation, after having swabbed the conjunctiva with silver nitrate solution, 2 per cent., an hour previous to the operation. I have never seen any untoward occurrence after this procedure.

In order to overcome the nervousness which many patients feel when suddenly introduced into the completely strange atmosphere of the operation room, it is an invariable practice to put the patient on the operating table the day before the operation and teach him to look at his own hand, being the opposite one to the eye to be operated on, held up in front of him. At the operation a nurse holds up the patient's hand upon which the patient himself fixes his gaze. In this way we avoid telling the patient to look down to his feet, together with the consequent dangers of this procedure. The skin of the area surrounding the operation is painted with tincture of iodine; the orbicularis is then infiltrated with novocaine solution, 1 per cent., above and below the palpebral fissure; this greatly helps in keeping the patient quiet, and I have had far fewer unruly patients since I carried this out.

When the patient is placed on the table the conjunctiva is bleached with adrenalin chloride solution, and then the conjunctival sac is thoroughly flushed with lotion from an irrigator above the level of the patient's head. The fluid used in Egypt is invariably freshly prepared surgical eusol solution, made from bleaching powder which has been kept in an air-tight receptacle; unless this smells strongly of chlorine it is inert, and only useful by its mechanical effect. It is not dangerously irritating to the bleached and anæsthetic conjunctiva.

As I have been talking mainly of hospital patients I have omitted to mention the massage of the lids to get rid of excess of Meibomian secretion, which I practise for private cases a day or two before the operation. I have found it advisable but not always easy to get this carried out in hospital practice.

The Operation as Usually Performed in Egypt.

In describing to you the variety of cataract operation which is usually performed in Egypt, or was being performed while I was still Director of Ophthalmic Hospitals, I must remind you that I was invited to occupy that post in order to teach ophthalmology, including especially the operative side, to Egyptian surgeons, and not in order to perform an immense number of operations myself. It has therefore been my object to fix in the minds of my pupils, by usually practising it, what I considered to be the safest operation for the average operator. I have naturally had opportunities of performing most of the different operations, but the operation which I now do is, I consider, the safest both for myself and my pupils. I think that each operator should do that operation which suits him best, and which he can do in the least time, with the least possible damage to the tissues. Certainly since my return I have seen some beautiful operations performed by other surgeons by very different methods. In any case the surgeon must be ready to alter his procedure to suit the exigencies of the case.

I open the lens capsule with a Dalrymple's cataract needle which has a perfectly cylindrical shaft, without escape of aqueous. I make a fairly large section, including a small conjunctival flap. I then remove the speculum and deliver the lens, depressing the posterior border of the wound with a curette, and just touching the lower part of the cornea with the concavity of a strabismus hook. During this manœuvre the lids may be separated by the assistant with a strabismus hook under the upper lid, and his thumb on the lower lid. I frequently wash out the anterior chamber with normal salt solution which has been filtered and boiled immediately previous to the operation to remove soft cortex. Some years ago I had bad results after washing out the anterior chamber, but none since I have attended to the preparation of the solution myself. I use a syringe with a flat silver nozzle in preference to any apparatus which requires an assistant. A button-hole iridectomy in the periphery of the iris is then performed, the iris forceps used being straight and without teeth.

I believe that the presence of the intact iris is a great safeguard against rupture of the hyaloid membrane and consequent loss of vitreous during delivery of the lens. I prefer to make a button-hole iridectomy rather than to leave the case as a simple extraction, as I think that there is less liability to prolapse of the iris when there is an aperture in it through which aqueous can escape, in case the anterior chamber reopens. The intention to leave intact the pupillary border of the iris is also guided by the desire to prevent the possibility of the prolapse of capsule into the wound rather than by the desire to obtain a better cosmetic effect. I have no hesitation in doing a complete iridectomy if the iris does not seem to go back easily into the anterior chamber on irrigation; at all times I prefer to do this if there is a reasonable probability of prolapse occurring subsequent to the operation. A drop of atropine solution is instilled and both eyes are bandaged. A metal shield of some kind is placed over the dressing. At every dressing the strictest aseptic precautions are observed, as regards the surgeon's hands, the sterilisation of the dressings, and of the atropine drops. Carelessness in this respect is invariably punished sooner or later by signs of inflammation. I find that old patients with bronchitis or restless people usually remain much quieter if they are taken from the operating room and placed in a deck chair with a pillow under the head, than if they are put to bed and told not to stir under penalty of losing the good effect of the operation. I remove the pad from the eye unoperated on at the first dressing. I flush the conjunctival sac with antiseptic drops and after drying them up instil a drop of atropine solution daily. Dark glasses are given between the sixth and tenth days.

By whichever method the capsule is opened, whether by the point of the knife, capsule forceps, the needle, or the cystitome, a number of cases will require discission of capsule subsequently. If the membrane is really anterior lens capsule it may be needled at any time after vascular congestion has disappeared. I have made a practice of needling such capsules ten days after the operation of extraction, provided that there is no redness. It must be very distinctly stated that the needling operation which I do is a very delicate affair, and consists in a single cut or tear of the membrane with a Dalrymple's needle. If an aperture is produced all is well, but if an aperture is not produced, either through clumsiness or through the membrane being thicker than was expected, no more is done, and it is dealt with on a subsequent occasion, as soon as all redness has disappeared. I occasionally use a Zeigler's knife, or a fine Graefe's knife, or more rarely two needles.

---

* Read at the Ophthalmological Section of the Royal Society of Medicine.

Sometimes one sees cases in which, owing to inflammatory conditions after the extraction, or owing to proliferation of the cells of the anterior capsule, the capsular membrane is thick and difficult to divide without causing dangerous traction on the ciliary body. I have no doubt that such cases are best dealt with by capsulotomy with de Wecker's scissors, an opening into the anterior chamber having been made with a keratome. I expect to do such operations without loss of vitreous. This operation should never be performed until a period of three months has elapsed since the last sign of inflammation in the eye disappeared.

In Egypt, where there is so much acute conjunctivitis with resultant corneal ulceration and disintegration of the globe, shrunken globes are very common, and one is frequently asked to extract a cataract in an eye which is fairly healthy otherwise, but in which the fellow eye is in a condition of phthisis bulbi. Now, as a matter of clinical experience, it is found that intra-ocular operations in a fairly good eye are frequently followed by iritis if the other eye is shrunken; also that sympathetic ophthalmia is a not unusual occurrence in a patient who has had a perforating ulcer of the cornea with prolapse of iris. I therefore invariably refuse to operate on the cataractous eye until its fellow, being in a condition of phthisis bulbi, has been removed.

I have not mentioned the importance of the routine examination carried out by the ophthalmic surgeon in charge of the hospital, all details being scheduled, including a note on the hæmoglobin percentage and the condition of the teeth. If the hæmoglobin is low, examinations are made for the ova of bilharzia, or ankylostoma, and if positive, the conditions are treated. Carious stumps are extracted by the surgeon, and if the frequent pyorrhœa alveolaris is present the gums are thoroughly swabbed daily for a period with tincture of iodine. Each cataract patient is given a toothbrush and is taught to use it with a solution of permanganate of potash. Before operation I always verify in the dark room the clinical notes made by the surgeon in charge of the hospital. My impression is that complicated cataracts are more common in Egypt, and it is easy for a surgeon of only two or three years' ophthalmic experience to miss an important sign, such as a faint tremor of the iris, which may be of the greatest importance to the operator or to the prognosis.

All cases of cataract extraction are examined and ordered appropriate glasses, if necessary at the Government expense. The fellahin, however, are usually satisfied with their unaided vision. If a patient does not come for examination he is sent for. In this way an exact record of the operative result is obtained. In order that each operator shall have a knowledge of his results it is insisted upon that he keeps a statistical record; this is also important for the purpose of clinical supervision.

Visual Acuity after Operation.

The visual acuity after cataract extraction in Egypt is usually poor as compared with that obtained in England. This is due to several reasons: First, the cornea is rarely clear, but has a leucoma, or nebula, or pannus; second, the intelligence of the patients in the country districts is frequently very undeveloped; and third, many even of the well-educated classes think it is bad luck to acknowledge how good their visual acuity after operation really is, though they may readily say that they are very pleased with the result. Also many cases of cataract in which the cornea seems to be clear when examined in the dark room before operation exhibit opalescence at the first dressing, due, as I suppose, to a refilling of old pannus vessels.

Difficulties Encountered in Egypt.

The operation of cataract extraction seems to be more difficult in Egypt than in England. The acquisition of sufficient Arabic for operative purposes is not a difficult matter, though a very necessary one, the difficulty being in the inability of the patient to sustain for the duration of the operation the required pose and immobility. On looking through my private notes I find several cases in which this is exemplified.

Case No. 13808, operated on at Asswan on March 25th, 1911, was a Berberine woman who understood no Arabic; she moaned and squeezed, and kept her eyes turned up during the whole operation. She was discharged from the hospital a month later with a clear gap in the capsule; impossible to take her vision, but she is able to get about well without glasses.

Case No. 6082, operated on at Zagazig on Feb. 14th, 1915; the patient squeezed as soon as the section was completed, the lens shot out in its capsule followed by vitreous. Iridectomy was done and the wound was sutured.

Case No. 14809, operated on at Damanhur on June 29th, 1911. After normal delivery of the lens the wound began to gape; the patient then squeezed, allowing a large escape of vitreous; the wound was closed with the ciliary body in view. Six weeks later the vision with sph. +9 and cyl. +4 was 6/36; the usual pre-existing nebula was present, and there was a fine capsular membrane.

The operation which I was in the habit of performing at this time was extraction with *iridectomy*, the capsule being opened with capsule forceps.

Case No. 8350, operated on at Medina-el-Fayum on March 16th, 1918. I failed to open the extraordinarily thick capsule of a Morgagnian cataract either with the point of the Graefe knife as it went across the A.C. in making the section, or with the cystitome. I therefore inserted the toothed iris forceps into the A.C. with the intention of tearing the capsule; however, the capsule was too tough to be lacerated, and I slowly withdrew a bladder-like Morgagnian cataract without loss of vitreous. The vision a fortnight after the operation was 6/24 with correction, the usual pannus being present.

I have notes of nine cases between 1916 and 1923 in which the lens was extracted with Macnamara's cataract spoon without losing vitreous. This was done in each case because some particular danger threatened, and not as an operation of election. A typical case was the following:—

No. 5304 was operated on at Rod-el-Farag, Cairo, on July 22nd, 1923. Extraction of cataract in a glaucomatous eye; the wound had to be enlarged, as owing to the shallow A.C. it was impossible to make the section adequately large; the capsule was opened with the cystitome. On commencing delivery of the lens the vitreous bulged; the lens was therefore scooped with Macnamara's spoon without loss of vitreous. A fortnight later the eye was quite quiet, the pupillary area being occupied with thick capsule for needling.

Another case of interest to me was No. 9901, Assiut, on which I operated on Sept. 28th, 1912. I found at the first dressing on the following day that the conjunctivo-corneal flap (at this time I was in the habit of making only a very small conjunctival flap) was anteflexed forwards on to the cornea. I therefore sutured it into position. Thick capsule was needled on Oct. 8th, or ten days after the extraction, after which the patient's vision with sph. +10 was 6/9.

It is certainly well to be prepared to suture the conjunctival flap in position if it shows signs of mal-apposition at the close of the operation. Recently I operated on a retired prize-fighter who exhibited signs of severe former injuries in a deflected nose and a pair of cauliflower ears. The cataract was about complete, while the other eye showed a posterior polar opacity, without, however, vitreous opacities. After section I opened the capsule with a cystitome and commenced delivery of the lens when vitreous protruded. I then did a complete iridectomy, and scooped the lens with slight vitreous loss. The wound gaped considerably so I put in two conjunctival sutures. At the first dressing in three days' time the eye was found to be perfectly quiet, but at the site of the wound the conjunctiva was bulging. I took a depressed view of the case, but he was discharged from the hospital within a fortnight with a perfectly flat wound, *a normal fundus as far as can be seen, and no* vitreous opacities. To me this case was interesting, as if I had not had the necessary sutures and skilled assistance I believe that the eye would have been lost.

These cases with exceptional operative conditions are not often met with, but it is as well to be prepared for the worst.

Operation in a Glaucomatous Eye.

I have already referred to a case of extraction of a cataract from a glaucomatous eye. By this I mean either as a primary operation or as a secondary operation after a previous decompression operation. In Egypt it not infrequently happens that a lens which exhibits slight opacity rapidly becomes totally opaque after a decompression operation, which, as far as can be seen, has been perfectly performed, certainly in which no injury to the capsule of the lens can be detected. I suppose that some change in the nutrition of the lens must take place as the result of the reduction of tension, causing it to become opaque. I referred to this in my report for the year 1919 of the Ophthalmic Section of the Department of Public Health. I there gave details of *ten such cases, all* those on which I operated for this condition between December, 1909, and February, 1918. In no case was vitreous lost, *and in seven of them useful* vision resulted. During the same period 59 similar cases were operated on by my assistants with loss of vitreous in 8 cases, *and resulting useful* vision in 41 cases. It therefore seems that it is worth while attempting operation in such cases provided that even a small *field only* remains.

Forms Peculiar to Egypt.

There is a form of cataract found in children in Egypt which is rarely met with in England or in Europe. It is not congenital, for there is invariably a history of previous good vision, followed by a rather rapid diminution, over a period of two to six months. The condition is usually binocular, but monocular cases are sometimes seen, in which the healthy eye shows no sign of opacity. The condition has long been known to be associated with anæmia, but was first fully described by Granville Waddy in the *Bulletin* of the Ophthalmological Society of Egypt for 1914. The principal causes of anæmia are ankylostomiasis and bilharziasis, with which the disease pellagra is in severe cases sometimes associated.

Some of these cataracts contain little more than a milky fluid, so that after opening the lens capsule the opaque matter can be evacuated by paracentesis, leaving the lens capsule to be dealt with later by needling. Other lenses consist of gelatinous material which can be easily broken up with the cataract needle, and then evacuated at the same sitting through a keratome incision. More rarely the substance of the cataract resembles that of the normal lens, and should not be evacuated until the aqueous has had time to break down the lens fibres.

A moderate degree of anæmia seems to have no adverse influence on the prognosis of intra-ocular operations. Such operation wounds heal with extraordinarily little increased vascularity, and usually without the signs of iritis. The cause of the anæmia in ankylostomiasis has not been fully worked out. It is not due to hæmorrhage from the intestine, or to ingestion of blood by the worms. It has been shown by Boycott and Haldane that the volume of the blood in ankylostomiasis is increased to double the normal, while the oxygen-absorbing power is about normal. It is probable, though it is not proved, that the worm secretes a toxin, which, being absorbed by the human host, causes inhibitory changes in the blood-formation of the red marrow. The severity of the anæmia is not always proportional to the number of worms present. The treatment of the disease has recently been revolutionised by the discovery of the vermicide properties of carbon tetrachloride.

THE INDUCTION OF PREMATURE LABOUR.*

A RECORD OF SEVENTY-TWO CONSECUTIVE CASES.

BY FRANCES IVENS, M.B., M.S. LOND.,
CH.M. LIVERP.,
HON. SURGEON, LIVERPOOL MATERNITY HOSPITAL; CLINICAL
LECTURER IN OBSTETRICS AND GYNÆCOLOGY,
UNIVERSITY OF LIVERPOOL;
HILDA CANTRELL, M.B., CH.B. LIVERP.,
AND
J. K. REID, M.B., CH.B. LIVERP.,
OBSTETRIC ASSISTANTS.

History.

THE first record of an induction of premature labour is that by Louise Bourgeois, midwife to Marie de Médicis in 1608. In 1756 a conference was held in London to discuss the frightful mortality of Cæsarean section, when Denman suggested induction of premature labour by rupture of the membranes as a therapeutic measure. Macaulay, of London, was the first to perform the operation on the wife of a linen draper in the Strand. In 1830 Kiwisch, of Wurzburg, introduced the method of induction by repeated douches of hot or cold water. In 1852 *Barnes made use of an hourglass-shaped rubber bag* with stopcock. In 1855 Krause introduced a method of induction by the insertion of a flexible bougie *into the uterus. A few years later*, in 1888, *Champetier* de Ribes's bag was invented, but could only be used after dilatation of the cervix. Small bags of very thin indiarubber were devised by Horrocks, of Guy's Hospital. Galabin approved this method, which he considered to be the most perfect, since it has the advantage, as compared with the use of the bougie, that there is very little risk of separating the placenta. The only difficulty is to get rubber bags made thin enough to dilate easily by hydrostatic pressure and yet strong enough not to burst.

Other methods, such as ecbolic drugs, separation of membranes from lower uterine segment, massage of breast or uterus, injection of glycerine between membranes and uterine wall, electricity, cervical tampons, have also all been used, but have nearly all been discarded with the exception of the quinine and castor-oil method, which is only successful in a small proportion of cases.

Propriety of the Operation.

The question of the propriety of the operation has been much discussed, more especially in cases of minor pelvic contraction. Williams thinks it has lost popularity in America owing to the high fœtal mortality. He himself has only done one case. In 301 operations by Ahlfeld, Bar, Leopold, and Pinard the fœtal mortality was 13 to 45 per cent., though the maternal mortality was only 1·03 per cent. They therefore held that it was no longer justified, and that equally good results for the mother, and far better for the child, would be obtained by subjecting the patient to the second stage of labour and resorting, if necessary, to Cæsarean section. Kleinwachter concluded, after an exhaustive study of the subject, that 78·3 per cent. of children were born alive, but only 60·4 per cent. left hospital alive. He considered that probably half of these born alive would die during the first year owing to unfavourable environment. He thought the operation should be abandoned, except when the child is abnormally large from excessive development or undue prolongation of pregnancy. Sarwey, in *2200 cases*, found a maternal mortality of 1·4 per cent., and 0·6 per cent. of this was due to infection, not necessarily due to manipulations. The infant mortality was 30 to 60 per cent. In the Queen Charlotte Hospital records in 10,000 labours there were 200 inductions. There was no maternal mortality, but 26 infants did not survive—viz., 12·6 per cent. Von Herff records 120 consecutive prophylactic inductions by rupture of the membranes, with a fœtal and infantile mortality of 20 per cent. In four years at the Liverpool Maternity Hospital (1916 to 1919), of 169 bougie inductions with no maternal mortality 171 children were born, with 25 fœtal and neonatal deaths—viz., 14 per cent. Prof. H. Briggs recorded in 1922 a series of 159 conservative bougie inductions in minor degrees of contracted pelvis, or fœtal over size, with eight stillbirths and five neonatal deaths—viz., approximately 8 per cent. Prof. Briggs regards induction favourably.

---

* A paper read at a meeting of the North of England Obstetrical and Gynæcological Society.

Most authorities, in discussing the induction of premature labour, state that the child requires greater care than a full-time child, and that the ultimate chance of life of the premature infant must be carefully considered. Prophylactic induction is most likely to be successful when pregnancy has advanced to the thirty-sixth week, and the conjugate of the brim measures at least 3½ inches. Some think labour should not be induced in a first pregnancy, but only with the history of previous difficulty or loss of child. The proper time must be determined by estimation of the relation between the size of the pelvis and that of the fœtal head, and the operation should be carried out as soon as there is difficulty in pushing the head in (to allow for the reduction for moulding). Eden advocates an examination under anæsthesia for the measurement of the diagonal conjugate, and the determination of the relative sizes of the head and pelvis.

Methods of Induction.

With any method it may be difficult to excite effective uterine contractions. There is no doubt that in some cases there is a personal idiosyncrasy, as in one of the cases included in this series, in whom, in two consecutive inductions, five days elapsed before labour pains started.

In our series of cases we chose the method considered by Galabin to be the most perfect—viz., the thin rubber bag—which we have employed in the form recommended by Prof. C. G. Lowry, of Belfast—viz., the toy balloon—distended by sterile water. With this method there is less risk of rupturing the membranes than with the bougie, the normally situated placenta is not interfered with, and there is less risk of carrying sepsis into the upper portion of the uterus. The insertion of the hydrostatic bag imitates closely the natural onset of labour and interferes little with its normal progress. The thin toy balloon is easy to insert, and there is no need for preliminary dilatation. If not more than 16 ounces of fluid are used there is no over-distension of the lower uterine segment. With the thin rubber bag there is very little displacement of the presenting part. The balloon can be boiled, so there is less risk of sepsis than with a gum elastic bougie, which cannot be so efficiently sterilised. It does not project from the vagina, so there is no ladder for the ascent of organisms.

The use of an anæsthetic is not a disadvantage. Though not essential it enables the examination to be more completely satisfactory, and a higher degree of asepsis to be attained, and it helps to remove the principal difficulties in induction of premature labour—viz., the recognition of the case requiring it, and the choice of the correct time.

Technique.

A general anæsthetic is employed. The vagina is douched with 1 in 2000 biniodide of mercury lotion and the uninflated balloon introduced with bullet forceps through the cervix, which is fixed by means of a modified Collin's lung forceps. Sixteen ounces of sterile water are introduced with a piston syringe through tubing tied on a glass tube in the neck of the balloon. The tubing is tied and a gauze pack left in the vagina to keep the tubing from projecting. The balloon and its connexions should always be previously tested.

Cases of Induction of Premature Labour.

The present investigation comprises 72 consecutive† cases, which were under observation during the years 1923 and 1924 at the Liverpool Maternity Hospital and Maternity Home.

Seventy-four infants were born, including two pairs of twins. Of the 72 inductions, 30 were primigravidæ and 42 were multigravidæ. In 65 of these cases delivery was effected per vias naturales, while seven were delivered by Cæsarean section.

In these 65 successful cases the average *period of gestation* was 38$^{1}/_{5}$th week (primigrav., 38$^{2}/_{5}$th weeks, multigrav., 38$^{1}/_{15}$th weeks).

The average *weight* of the children was 6 lb. 12 oz. (primigrav., 6 lb. 8½ oz.; multigrav., 6 lb. 14 oz.), and the average length 19·2 in.

The average *time from induction* until pains began was 8 hr. 20 min. (primigrav., 7 hr. 12¼ min.; multigrav., 9 hr.). As a comparison, in four years (1916–19), in 169 bougie inductions at the Liverpool Maternity Hospital, the average time from induction until pains began was 24 hours, almost three times as long. With the balloon inductions the average time from induction until delivery was 29 hr. 17 min. (primigrav., 30 hr. 9 min.; multigrav., 24 hr. 31 min.).

In the Liverpool Maternity Hospital reports 1916–19 as above, the duration was 46·6 hours, which is nearly double. The average length of time from induction until pains began and until delivery was much prolonged by two cases, one a primigravida who had no true labour pains for 110¼ hours, and a multigravida who had no true labour pains for 183¼ hours. Excluding these two cases the average length of time from induction until pains began was 2 hr. 47 min. in the primigravidæ (hospital cases) and 3 hr. in the multigravidæ.

General anæsthesia was employed in all cases but two multigravidæ with cardiac disease. The indications were: (1) a minor degree of pelvic contraction, 63 cases; (2) post-maturity and large fœtus, 6 cases; and (3) maternal disease, 5 cases (3 cardiac, 2 toxæmias).

Pelvic Measurements.—In 41 cases there was a minor degree of general contraction, the diagonal conjugate averaging 4·4 inches. Eighteen of these cases were primigravidæ with an average D.C. of 4·3 inches. Twenty-three were multigravidæ, averaging 4·4 inches. The smallest D.C. in a primigravida was 3·8 inches. In 22 cases there was a minor degree of flattening, the D.C. averaging 4·3 inches. Nine of these were primigravidæ, giving an average D.C. of 4·5 and 13 multigravidæ giving an average measurement of 4·2.

Results.—1. Natural delivery took place in 52 cases. 2. Delivery by forceps in nine cases. 3. Delivery by Cæsarean section in seven cases.

Forceps Cases.

CASE.
2. P. Flat pelvis. D.C. 4¼. R.O.P. Infant 6 lb. 12 oz.
12. P. Second twin. Uterine inertia. Infant 6 lb. 4 oz.
17. M. First induction failed. D.C. 4¼. High forceps. Infant 6 lb. 2 oz.
37. P. Prolonged second stage. Low forceps. Infant 6 lb. 1 oz.
46. P. 134 hours before labour began. D.C. 4¼. Mid. forceps. Fœtal stress. Infant 7 lb. 8 oz.
49. P. D.C. 4¼. Prolonged second stage. Low forceps. Infant 6 lb. 12 oz.
56. P. D.C. 3¾. Hyperemesis. Hæmorrhagic vomiting. *B. coli* infection. High forceps. Stiff pull. Child died of meningitis fourth day. No intracranial injury. Weight 6 lb. 1 oz.
64. M. D.C. 4¼. History of stillbirth and septicæmia. Toxæmia during pregnancy. Streptococci in urine. High forceps. Infant 9 lb. 8 oz.
68a. P. D.C. 4¼. Rigid cervix. Hydrocephalic infant with spina bifida. Stillbirth. Weight 4 lb. 13 oz.

Delivery by Cæsarean Section.

20. P. D.C. 4¼. Slight pains 4 days. No advance. Cæsarean. Weight 6 lb. 12 oz.
25. P. D.C. 4. Pelvic presentation. No advance in 3¼ days. Cæsarean. Weight 6 lb. 7 oz.
31. M. D.C. 4¼. Two previous forceps. L.O.P. Uterine inertia. Cæsarean. 6 lb. 2 oz.
41. M. D.C. 4¼. Flat. Four forceps. One previous induction at 37 weeks. Induction. Transverse lie. Cæsarean section 23 hours after induction. Infant 7 lb. 2 oz.
44. M. Ten normal. 11th stillbirth. 12th lived one hour. 13th forceps. 14th balloon induction twice, followed by bougie induction. Uterine inertia. Cæsarean section by Dr. Willett. 6 lb. 13 oz.
54. 2-gravida. Previous delivery of 8 lb. infant after balloon induction. D.C. 4¼ in. Uterine inertia. Head remained above brim. Cæsarean. Infant 7 lb. 2 oz.
65. 2-gravida. First child normal delivery of infant 6 lb. 2 oz. D.C. 4 in. Contracted outlet. Full dilatation. Head above brim. Weight 8 lb. 5 oz.

---

† In this series a fatal case of eclampsia where induction was done at the thirtieth week is not included.

Pelvic Presentations.

There were eight pelvic presentations, of which three were born normally, and one by Cæsarean section. There was difficulty with four cases.

CASE.
33. P. D.C. 4½. External version had failed. Delivered with difficulty of living child. Weight 7 lb. 3 oz.
61. P., with slight contraction and premature rupture of the membranes. Uterine inertia. Balloon induction. Four hours later balloon expelled followed by infant with extended legs. Weight 5 lb. 7 oz.
72. P. D.C. 4½. Extended legs and arms brought down with difficulty. Weight 6 lb. 10 oz.
12. P. Twins. D.C. not reached. Difficulty with after-coming head. Stillbirth. Second twin forceps delivery. Weight 5 lb. 10 oz.

Malpresentations.—In one case already mentioned (Cæsarean section) a transverse lie occurred (Case 41). In another (Case 10) M., with previous difficult forceps delivery—after expulsion of balloon head remained high, hand and cord presenting, bag of membranes at vulva. Presentation was rectified under anæsthesia. Normal delivery 40 minutes later.

Results.

Mortality.—All the mothers survived. Of the 74 infants 72 were born alive—viz., all except the first twin in two cases, one being a hydrocephalic monster, and the other a pelvic presentation in a primigravida where there was difficulty with the after-coming head.

Neonatal Deaths.—1. One of meningitis (fourth day). 2. One of diarrhœa and vomiting (twelfth day). Breech. Weight 7 lb. 5 oz.

All the infants therefore but four—viz., 5·1 per cent.—left the hospital alive. Of the 70 living infants, 58 have been traced, and 55 are alive. Three are known to have died in the first year: (1) Enlarged thymus, five months. (2) Convulsions and wasting, six weeks (breech). (3) Marasmus at three months. (This infant was the second twin to stillborn hydrocephalic infant) (also a breech). Of the 71 infants the ultimate known mortality is 9 per cent.

Morbidity.—Morbidity occurred in one mother (No. 61). This patient was a 2-gravida. D.C. 4½. The first child was a difficult forceps delivery with ruptured perineum which had not united, followed by septicæmia. Toxæmia with albuminuria was present during pregnancy. Induction was deferred on account of the history until $40^{6}/_{7}$th weeks, when the size of the child made it imperative. The large child, 9 lb. 8 oz., was delivered alive by high forceps operation (Tarnier's axis traction). Antistreptococcal serum was administered, and a bacteriological examination of the urine taken before delivery revealed streptococci. The temperature remained high for a few days, but the patient ultimately made a good recovery.

Special Points.—With a balloon induction, as with any other method, it is especially necessary to eliminate the possibility of latent sepsis, of gonococcal or streptococcal origin. It is important for the nurse in charge to note whether the head is following the balloon, and if not to push it into the pelvis.

Conclusions.

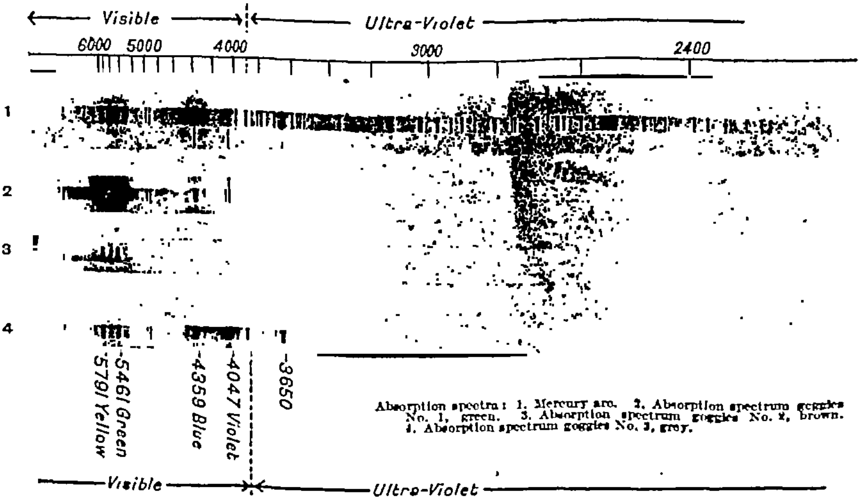
That by the induction of premature labour in suitable cases a considerable amount of unnecessary suffering from prolonged labour due to minor pelvic contraction may be avoided. In addition, induction of premature labour is not so inimical to the child as published statistics maintain.

THE SPECTROSCOPIC EXAMINATION OF ULTRA-VIOLET GOGGLES.

BY B. D. H. WATTERS, M.Sc.,
PHYSICS DEPARTMENT, MIDDLESEX HOSPITAL.

THE question of the quality of the goggles worn by operators when working in ultra-violet light is one which has scarcely received proper attention. These goggles have often to be worn for long periods, and they should transmit the maximum amount of the visible radiation, so as to allow the user to see the room and all apparatus, &c., perfectly clearly whilst every trace of ultra-violet is absorbed. Glass which fulfils both of these requirements is obtainable without difficulty, but a number of the goggles sold for this purpose are fitted with very inferior glass which often falls short on both counts.

A specimen was examined recently, as the operator who had been using them complained of headache and eyestrain after quite a short exposure. On taking a photograph of the absorption spectrum on a panchromatic plate, in a quartz spectrometer, the cause of the trouble was at once apparent. (See Fig. 4.) This glass transmits a considerable portion of the ultra-violet spectrum to about λ3500, thus allowing the intense mercury line at λ3650 to pass with very little diminished intensity. At the same time the lines of the visible spectrum are partially absorbed, giving rise to the dark-grey colour of the glass. Not only are the goggles unnecessarily dark in



Absorption spectra: 1. Mercury arc. 2. Absorption spectrum goggles No. 1, green. 3. Absorption spectrum goggles No. 2, brown. 4. Absorption spectrum goggles No. 3, grey.

tint, but, what is much worse, a dangerous quantity of ultra-violet light is transmitted.

That radiation of this wave-length is harmful can easily be proved by isolating it by a suitable filter, when it is found to cause a most painful sensation in the eyes if the exposure is longer than a few seconds. At the same time it will be noticed that the eyeball fluoresces brilliantly.

The grey goggles were replaced by a pair of light-green tint whose absorption spectrum is shown. (See Fig. 2.) The difference is strongly marked. The yellow and green light which is so strong visually is transmitted almost without absorption, the blue to a less extent, and the violet still less. No trace of any radiation is to be recorded even by prolonged exposure beyond the limit of the visible spectrum. These goggles have proved very satisfactory in use—everything in the room was clearly visible, and all painful sensation in the eyes completely disappeared.

For purposes of comparison the spectrum of a third pair is included (See Fig. 3.) These were brown in colour and transmitted only the yellow and green of the visible spectrum, whilst a faint trace of the ultra-violet line λ3650 will be noticed. The latter, however, is too weak in this case to have any perceptible effect. This pair of glasses may therefore be classed as not quite so good as the green ones, but probably quite efficient in use, and very much better than the original grey ones.

To summarise, it is clear that the mere visual examination of a pair of goggles is quite insufficient to indicate their suitability or otherwise for use in ultra-violet work—a spectroscopic examination is essential.

Clinical and Laboratory Notes.

A CASE OF SPONTANEOUS PNEUMOTHORAX.

RAPID AND COMPLETE RECOVERY.

By F. H. KELLY, M.B., B.S. LOND.

CASES of spontaneous pneumothorax, apart from those occurring in the course of active tuberculous disease of the lung, are not always characterised by a prolonged course or by a bad ultimate prognosis, as the following case shows.

The patient was a thin and slightly-built man aged 32. There was no history of previous illness, and he had served through the war without trouble. On the morning of Feb. 26th last he experienced sudden pain in the region of the sternum whilst stooping down after breakfast. He worked all day although the pain continued, and he had considerable shortness of breath.

Condition on Examination.—When seen for the first time on the 27th he had obvious signs of complete left pneumothorax. The left side was increased in size as compared with the right, but moved less. The percussion note showed increased resonance on the left side but was not tympanitic. The lower limit of resonance at the back was 2 in. lower on the left side than on the right. There was complete absence of vocal fremitus and vocal resonance on the left side. There was no cardiac dullness in the usual place, its left edge appearing to coincide with the right edge of the sternum. The apex beat could not be felt, but the position of maximum intensity of the heart sounds was exactly in the mid-line of the sternum. There was obvious dyspnœa even when lying in bed, and this was markedly increased by even gentle movement. The pain was not severe so long as the patient kept quite still.

Up to April 4th, on which day the patient was seen, there was practically no change in the condition of the chest. The left side became gradually a little less resonant, but was still distinctly more so than the right. At the back the lower limit of resonance was now only 1–1½ in. lower on the left side than on the right. The position of the maximum intensity of the heart sounds was still approximately in the middle line, but was a little difficult to locate owing to the development of a loud slapping extra-cardiac sound, due presumably to the forcing together of two pleural surfaces by the heart's action. During this time the patient had gradually been promoted to getting up one hour a day, pain had disappeared, and dyspnœa was much less. The temperature, taken each evening at 6 o'clock, had never exceeded 98° F.

On April 6th, five weeks and four days after the onset, the cardiac dullness was found to be restored to its normal position, the apex beat was ½ in. internal to the nipple line, all the signs described above had disappeared, and in fact the chest appeared to be in all respects normal except that the breath sounds on the left side were not so good as on the right (this difference disappeared in a few days). The contrast from the condition only two days previously was amazing.

The subsequent progress of the case has been one of uninterrupted recovery. No abnormal signs have been found in the chest on either side and the patient appears now (June 15th) to be perfectly fit and well in every respect. He started work again a few weeks ago.

Hurstpierpoint, Sussex.

A CASE OF CHRONIC MENINGITIS LASTING FIFTEEN YEARS.

By MARY HAMILTON WILLIAMS, M.B., B.S. LOND., D.P.H. CAMB.

THIS case is reported in order to suggest that there are more cases of intractable headache due to chronic germ infection of the meninges than is recognised.

Early History.—The patient, a married woman aged 55, had an early history of arrested pulmonary tuberculosis, malaria, and cerebro-spinal fever. A growth had been twice removed from the left antrum, and she had had a high degree of myopia. At the age of 40 the patient lost 3 st. in weight in less than a year, and this was ascribed to a probable recrudescence of tuberculosis. During this year she had attacks of partial loss of vision, occurring suddenly, and also saw flashes of white light, very brilliant, often appearing to resemble showers of falling stars. Sometimes the light was coloured and zig-zag. The flashes always appeared to the left eye. After one to two hours visual disturbance acute pain in the head set in. This was at first localised in the right occipital and parietal regions, and then diffused. There was also aphasia, nausea, acute photophobia, tenderness, and aching of the right cervical glands. During this year the patient lost two-thirds of her hair. The patient was examined by various consultants, who agreed that the trouble was probably tuberculous. Sir Victor Horsley diagnosed a meningitis 15 years ago, but considered it inoperable. The oculist diagnosed "typical migraine," and found bi-temporal limitation of fields of vision; fundus normal. These attacks at first occurred every six weeks, but gradually became more frequent.

Subsequent History.—As the years passed the patient lost strength, and any considerable fatigue brought on an attack. After an attack—not during—there was marked pallor of the face. Insomnia became very troublesome, whole nights being passed without sleep. There were also terrifying dreams. Either before or during an attack a period of extreme drowsiness would occur, lasting several hours, and not terminating in restful sleep. All possible means were tried to give sleep, as otherwise insanity would have been the termination. The patient continued to do brain-work, and did not consider that this tended to bring on an attack. But it was necessary to work in a warm room (70° F. for choice) and backing the light. Work which required lateral movements of the eyes—e.g., checking a catalogue—brought on pain. On waking in the morning, and sometimes during the night, there were jerky movements of arms, hands, legs, and feet. When the patient first drank in the morning there was sometimes acute pain at a special point which appeared to be about the cardiac orifice of the stomach, and the patient could not swallow until it passed.

After the attacks had continued during some five years it was noticed that before an attack there was frequently slight epistaxis, and during the attack there was constipation. After an attack ended pain was never again caused, for at least 48 hours, by exercise or exertion, which, at any other time, would have started pain with certainty. The temperature was always raised, being 99·4° in the morning and reaching 102° or higher on some nights. This was at the time ascribed to a recrudescence of tuberculosis. After about ten years had passed dyspnœa was first noticed, and the pulse was slow, 70–76, even with pyrexia. The attacks gradually became more frequent, and the patient reached a condition when she was never free from pain for more than a few hours, and the insomnia and dyspnœa grew worse.

Two unusually severe attacks made it evident that, if operation was not possible, the patient's life would be short. In these attacks there were great drowsiness and agonising right occipital pain; flashing in the left eye, acute dyspnœa, the pulse-rate varying from 58–60, and intermitting seriously, with absolute insomnia. Plantar reflexes not detected; Kernig positive. There was some flashing in the right eye. A few days later there was definite extensor response to plantar reflex. An area of acute local tenderness was present over the right occipital area, and there was also slight œdema here, lasting some hours. On each of these two attacks, after the head pain had lasted some hours, severe stabbing pains set in in the shoulders and back. A peculiar sensation and thrill in the muscles was also present. In addition to the dyspnœa there was great air-hunger, so that the patient only breathed happily in front of a large open window.

The patient was taken to London and Mr. Donald Armour decided, despite the absence of definite localising symptoms, and at the express wish of the patient, that he would operate.

Definite extensor plantar reflexes were found which often varied from day to day. There was some œdema, as before, and it was considered that this and the localised pain would suffice for localisation. Sufficient bone was therefore removed from the right occipital and parietal regions to allow for access to the cranial contents. Considerable fluid was found outside the dura mater, with great bulging of the meninges, the dura being under high pressure. The meninges were three to four times as thick as normal, and this area was removed. The cerebro-spinal fluid escaped under high pressure. No sign of tuberculoma was found. The scalp was replaced, leaving a large area without bone.

On recovery from the anæsthetic the patient said she felt as if she could not breathe and it was necessary to keep an electric fan working close to her night and day. (In a recent report of a post-mortem on such a case I noted that there were numerous small hæmorrhages found in the region of the vital centres in the medulla, suggesting a cause for air-hunger.) The condition took several days to pass off.

Post operative History.—After the operation photophobia was extreme and brilliant white sheets of light lasting for hours were distressing. Unfortunately it had been taken for granted that the germ causing the meningitis was the tubercle bacillus, and therefore no cultures were made. Since the operation the patient is much improved, the elasticity of the scalp preventing dangerous degrees of pressure occurring, but the insomnia and pain became again troublesome towards the end of last year, and a vaccine was made from the post-nasal region, after a most exhaustive negative X ray examination of all the head region. Dr. L. G. Mackey found an infection of pneumococcus and influenza and from this made a vaccine. Only small doses can be used, but the patient is again improving, leading a busy working life.

An uneducated patient would have been unable to give the descriptions which here helped this diagnosis. "Migraine" is a diagnosis of a highly unsatisfactory character, and the causal germs need ascertaining.

Colwall, Malvern.

DONATIONS AND BEQUESTS.—By the will of the late Miss Elizabeth Jane Humby, of Hamilton-terrace, St. John's Wood, the testatrix left, among other bequests, £100 each to the Royal National Sanatorium for Consumption, Bournemouth, the Western General Dispensary, Marylebone-road, the Royal Medical Benevolent Fund, the Royal Medical Benevolent Fund Guild, St. Mary's Hospital, Paddington, the Middlesex Hospital, and the Church Army; £50 each to the London Fever Hospital, the Hospital for Epilepsy and Paralysis, the Paddington Green Children's Hospital, and King Edward's Hospital Fund.

CONTRIBUTORY SCHEME AT IPSWICH.—A contributory scheme is about to be started by the East Suffolk and Ipswich Hospital. It is proposed to include not only industrial weekly wage-earners, but also the clerical staffs in the factories, the employees of shops and offices, and the one-man trader. An agricultural contributory scheme has been in existence for the last six years, each farm-worker giving a penny a week with a similar amount from his employer. During the last 15 years members of the board of management have subscribed £15,000 for the enlargement, improvement, and maintenance of the hospital.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BATH.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

THIS Section met on three days—Wednesday, Thursday, and Friday—Lady Barrett (London) occupying the chair.

WEDNESDAY, JULY 22ND.

MALIGNANT DISEASE OF THE PELVIC ORGANS.

Prof. B. P. Watson (Edinburgh), in an opening address on the

Problem of Cancer of the Uterus,

said that the toll this disease took of the population of the world was enormous, and although we did not know the cause, yet chronic irritation was so constantly present in cancer of the cervix that it must be recognised as one of the ætiological factors. Cervical cancer was ten times more common than uterine cancer, and it was essentially a disease of parous women He thought that the incidence of the disease could be diminished (1) by avoiding all procedures likely to cause cervical lacerations at childbirth; (2) by the thorough treatment, and, if necessary, removal of the existing lesions. Women should be made to understand that long-continued leucorrhœal discharge indicated a diseased condition, and called for investigation and treatment. He considered that operations such as a plastic repair or amputation of the cervix were very simple procedures and devoid of risk. In his opinion the more extensive employment of these prophylactic measures at or about the menopause would diminish the incidence of the disease and early diagnosis would lessen the mortality. Prof. Watson emphasised the importance of teaching students the necessity of thoroughly investigating every case of irregular vaginal bleeding in women of all ages, nor should they be satisfied until cancer was definitely excluded. He maintained that it was only by this means that the early cases would be recognised.

The speaker then proceeded to discuss the relative merits of operative and radium treatment in cancer of the uterus. He had formed the opinion that in a clearly operable case of cancer of the cervix operation preceded by radium treatment offered the best chance to the patient, but in border-line and advanced cases radium treatment was the only one that held out any hope. In cancer of the body, however, he thought that operation offered a better chance than radium treatment. He held that wherever the disease, and whatever the treatment employed, the chances of cure were in inverse proportion to the duration of the symptoms. Prof. Watson finally made a strong appeal for a widespread educational propaganda to be carried on amongst the people in order that the cases might be seen early. He did not think it would unduly alarm the women of this country, for ten years' work among women on the other side of the Atlantic had convinced him that more good than harm resulted from such knowledge.

Mr. Victor Bonney then read a paper on the

Operative Treatment of Carcinoma of the Uterus.

He said that he welcomed the opportunity of speaking on the operative treatment of carcinoma of the uterus because he had no doubt at all that, up to the present time, it remained the treatment of election for the majority of cases. Dealing first with carcinoma of the cervix he reminded his hearers that here, as in every other variety of carcinoma, the growth extended itself in two ways—tissue infiltration and lymphatic permeation, and the line of operative excision must, therefore, be planned so that whilst at all points it kept outside the margin of growth by infiltration, it was extended in the regions of lymphatic permeation as far outwards as the anatomy of the parts and the endurance of the patient would permit. The operation which fulfilled these requirements was that introduced by the

Viennese gynæcologist, Wertheim. From 1907 to the present day he (Mr. Bonney) had performed Wertheim's operation about 300 times, but since no figures bearing on the subject were of any value unless grounded on the basis of five years' freedom from recurrence he dealt only with the first 192 cases of the series. These cases should be looked upon as the number he was able to operate radically upon, out of 303 unselected patients seen by him between the years 1907–20. With so high an operability rate it followed that in a large proportion of the patients the disease was well advanced, and in many cases very advanced. In general, the only bars to the accomplishment of the operation that he had recognised had been deep and extensive involvement of the bladder or the bowel, or involvement of both ureters to the extent of producing bi-lateral hydro-ureter. He had found what others practising the operation had found—namely, that in many cases it was impossible to determine whether the growth was removable or not, except by opening the abdomen. The operation as performed by him had always been as drastic and radical as he believed it possible to perform while giving the patient a good chance of recovery. The uterus and appendages, the whole or practically the whole vagina, together with the parametric and paravaginal tissue occupying the obturator fossæ and the glands along the external iliac vessels were removed. As regards the vagina, he had extended the operation of recent years; originally removing the upper half only he now removed it entire in most cases, because, next to the lymphatics which run out to the obturator fossæ, the vaginal wall was the most important line of march of the cancer cells. His results were as follows: Died of the operation, 32 (an operative mortality-rate of 16 per cent.); died of recurrent growth, 70; died of other disease, 5; lost sight of, 7; well after five years, 78 (that is 40 per cent. of the whole series, or nearly 49 per cent. of the cases recovering from the operation, or 25 per cent. of all the cases seen, reckoning his operability rate at 63 per cent.).

The operative mortality was high compared with that of ordinary operations of surgery, but he could have reduced it by performing a less drastic operation and by refusing to operate on the many "last chances" he had undertaken. The likelihood of recurrence was greatest in the first two years, and progressively diminished from then onwards. Five years' freedom from recurrence used to be considered an absolute cure, but unfortunately that was not quite true, as a certain small number of recurrences (about 3 per cent. of all recurrences) took place after five years, the latest among his cases being six and a half years. In regard to the 78 cases reported as "well" after five years, the accomplishment rate of the operation depended upon the point of view from which it was considered. Thus, reckoning for the present purpose all these cases as cures, then out of the 303 unselected cases of carcinoma of the cervix seen by him between 1907 and 1920 25 per cent. were cured. Lastly, taking only these cases that recovered from the operation, there were cured just on 49 per cent. of the 160 patients who recovered from the operations performed between 1907 and 1920. In 78 of the cases the glands removed at the operation were carcinomatous, and it had been argued that where this was found to be the case it was useless, or usually useless, to proceed with the operation. Although the outlook for cases with carcinomatous glands obviously could not be as good as for cases in which the glands were not carcinomatous, it was by no means hopeless; 25·6 per cent. of the 78 cases operated on were well after five years and 33·3 per cent. of the 60 cases recovered from the operation. He did not use radium beforehand as a routine, though he had operated on a good many cases in which it had been so used with the idea of making the growth removable. Those who said it could do this did not know the limits of operability. It did nothing of the sort, but on the contrary made the operation much more formidable on account of the intense fibrosis set up which so welded the surrounding tissues to the growth that all planes of cleavage were lost and the separation of the bladder and ureters became a matter of great difficulty. Except in exceptional instances irradiation after the operation was not advisable, for the indiscriminate use of radiation without guide either as to direction or depth carried with it the very real danger of stimulating instead of killing any stray malignant cells that might have been left behind at the operation.

Turning to the surgical treatment of carcinoma of the corpus, Mr. Bonney said that the problem of diagnosing the disease must be given an important place. It was frequently necessary to explore the interior of the uterus under an anæsthetic, and even then it was sometimes impossible to scrape out anything worth microscopical investigation. Bleeding after the menopause should always be regarded as a menacing sign, and the likelihood of error should always be on the side of an interpretation too grave rather than too optimistic. The operation he performed was a free total hysterectomy, taking out the uterus, the vaginal vault, and both appendages, dividing the ovario-pelvic ligaments at the point where they take off from the pelvic brim. He only did Wertheim's operation in special instances. In his experience at least 50 per cent. of the patients recovering from operation were free from recurrence five years afterwards. This estimate was not based on accurate statistics, as he had not followed up these cases with the same thoroughness as in the case of those with cervical carcinoma.

Mr. S. J. Cameron (Glasgow) said that he intended to confine his remarks to

Cancerous and Sarcomatous Disease of the Ovaries and Cancer of the Fallopian Tubes.

He purposely omitted chorion-epithelioma and only briefly referred to the Krukenberg tumours of the ovary, which, in his opinion, were almost invariably secondary to cancer of the stomach. He based his paper on 94 unpublished cases. In his experience primary cancer of the ovary was much more uncommon than the secondary type, which, owing to its obtrusive size, had attention called to it, whereas the primary growth, being small and giving rise to no urgent symptoms, often remained unrecognised. Apparently the ovary provided a suitable soil for the implanted cancer cells, and, although it was generally accepted that the histological appearance of the secondary growth was the same as the primary, he had not always found this so. The speaker made a strong plea for the careful microscopic examination of all ovarian cystoma after removal, as a naked-eye examination might fail to reveal malignancy. The latter condition should always be suspected in a woman who had been in failing health for some time previously, and more especially if ascites were present. Sarcoma of the ovary was much less common than carcinoma, but the prognosis in either case was almost equally bad. Mr. Cameron drew attention to the difficulty of making an early diagnosis in these cases and hoped that Gye's recent work would make this possible in the near future. In referring to primary cancer of the Fallopian tubes, the speaker said that this condition was rare; he personally had only met with two cases. The diagnosis was difficult and the most prominent symptom was a copious watery discharge which might occasionally be blood-stained.

Discussion.

Mr. H. J. D. Smythe (Bristol) was interested to hear that Mr. Bonney now removed the whole of the vagina in Wertheim's hysterectomy. He agreed with Prof. Watson on the importance of the prophylactic treatment of cervical lesions, and stated that he always performed a pan-hysterectomy in these cases.

Prof. W. C. Swayne[1] (Bristol) said that Mr. Bonney had proved by his figures that the most radical operation in carcinoma of the cervix was the best. He agreed about educating the public, but thought that the propaganda could only be carried out by the general practitioner.

---

[1] The tragic death of Prof. W. C. Swayne was the subject of an obituary notice in THE LANCET of August 22nd, 1925 (p. 410)

Prof. F. W. Marlow (Toronto) drew attention to the value of slow cauterisation of the growth as a preliminary to operation. The technique he employed was a modification of the Percy method. It was safer than radium as it removed the focus of infection.

Mr. Sidney Forsdike (London) said that he had never found any great difficulty with prophylactic radiation in cancer of the cervix. He would be interested to hear the methods and technique employed by Mr. Bonney in these cases.

Dr. M. Donaldson (London) strongly protested against the sweeping statements made by some of the speakers who opposed the use of radium, although it was obvious that they had had very little, if any, experience of its use. He pointed out that one of the speakers condemned radium after seeing a few patients who had been treated by applications which lasted less than 12 hours.

Mr. Leith Murray (Liverpool) pleaded for the better training of midwives, as they were often consulted before practitioners in these cases.

Replies.

Several other speakers took part in the discussion, and Prof. Watson and Mr. Cameron briefly replied.

Mr. Victor Bonney deprecated the criticism of the results he had obtained in cases in which the regional glands were carcinomatous, where radium was incapable of effecting a cure. The advocates of radiation would, no doubt, say that the carcinomatous regional glands could be treated by deep X rays, but his experience of this treatment, both for primary and secondary growths, was most disappointing. He had seen many cases in which the growth was certainly delayed, but never once had he seen a cure. In short, the only cure for cases in which the regional glands were malignant was operative removal, and this being so he saw no point in girding against the results of a treatment which, though very far from ideal, was yet the only treatment which held out any hope. He submitted that to have "cured" 25 per cent. of these cases was an unexpectedly great triumph. If it were possible to recognise before the operation those cases in which the glands were carcinomatous he would not adversely criticise the surgeon who considered that, as a group, they were not worth operating on, seeing that the risk of the operation was great and the chances of permanent cure relatively small. He should not agree with such a view himself, but it would be a matter of personal opinion which every surgeon would have to decide for himself. It was, however, impossible to make such a distinction not only before the operation, but even during the operation, for until the glands were removed it was, in many cases, impossible to say whether they were malignant or not.

No one was more anxious than himself to find a better method of treating carcinoma of the cervix than operation, but there was no sense in the advocates of radiation carping at the results of surgery until they had produced a series of figures comparable with those he had just put before them. It was no use trading on foreign sources for such figures: a study of the literature showed how entirely discordant they were. What was needed was the publication of a British series of not less than 100 cases treated by radiation, in all of which at least five years had elapsed between the date of cessation of all treatment and the date of publication. The interval that had elapsed since the cessation of all treatment was of prime importance. There was a great difference between keeping a patient alive with a carcinoma and curing a carcinoma. When such a series, produced from a reliable British source, gave a better cure-rate than he had obtained by operation, then he would immediately cease to operate any longer and hand over all his cases of cancer of the cervix to the radiologists.

THURSDAY, JULY 23RD.

Prof. James Heyman (Stockholm) opened a discussion on the

Treatment of Inoperable Cancer of the Pelvic Organs.

He said that he intended to set forth the result of his experience at the gynæcological department of the Radium-Hemmett, Stockholm, during the 15 years of its existence. This institution was founded by the Swedish Cancer Research Society for the radiological treatment of cancer cases referred from other hospitals. Radium treatment had been almost wholly restricted to inoperable cases, with the exception of cancer of the cervix, where the figures submitted in the first published report (1920) had been so striking that the leading Swedish gynæcologists had since that date ceased operating for this condition. The speaker claimed that he could report on 100 per cent. of the cases treated. This had been made possible by organised control of the patients and by the fact that owing to a special Act of Parliament the Swedish Government paid the travelling expenses of the poorer patients to and from the Radium-Hemmett.

Cancer of the cervix formed the most important group, and during the years 1914–22 inclusive they had treated 440 inoperable cases of this disease with radium. Of this number 243 had been under observation for five years or longer, 80 of whom remained free from symptoms. This gave a figure of 10·7 per cent. of permanent cures amongst cases which would otherwise have been regarded as hopeless. In addition two-thirds of the cases had regained sufficient strength to resume work and nearly half of these had remained at work over a year. Inoperable cancer of the body formed a smaller group than the preceding one and included those technically operable cases which, on account of old age and pronounced adiposity, rendered them unsuitable for operation. Out of 54 such cases treated with radium between the years 1915 and 1922 inclusive, 17 had been observed for five years or longer; of these 10, or 58·7 per cent., had remained free from symptoms. Inoperable cancer of the vulva and vagina had not reacted well to radium treatment, and results obtained from the treatment of ovarian carcinoma were disappointing. Six cases of cancer of the urethra were treated—the results were not good.

Prof. Heyman then briefly referred to the technique he employed and the methods of treatment adopted. He always used radium salts which were filtered through 3–4 mm. of lead, and as a rule only three applications were made. If possible radium was inserted at each of these treatments both in the vagina and the uterus. He rarely combined the treatment with X rays, nor did he approve of previous curettage.

Mr. Percival Cole (London), who followed, confined his remarks to the

General Position and Treatment of Inoperable Cancer of the Uterus.

He said that the numerical importance of the subject before them was emphasised by the inoperability rate which he estimated at 62 per cent. Operability, or otherwise, of any particular case was generally decided by the extent of local invasion, and it was estimated that in 60 per cent. of cases of cancer of the cervix death occurred as the results of effects determined by what remained to the last a local lesion. The regional glands were involved in from 24 to 38 per cent. of cases. Mr. Cole gave an account of the result of his experience at the Cancer Hospital, London, where 203 cases of cancer of the uterus were admitted between and including the years 1910–25. Of the cases admitted 103 were treated with radium and 61 by the Percy cautery operation; only 12 per cent. of cases were operable and 40 per cent. were too far advanced for any form of treatment. In discussing the technique employed in radium treatment he emphasised the importance of using dosage and filtration suitable to the case. He had found that the use of needles and gauze packing had largely obviated the most important of the radium sequelæ—namely, proctitis, cystitis, and fistula formation. He did not approve of unfiltered glass capsules of radium emanation. He drew attention to the possibility of a violent hæmorrhage after the use of radium. This had occurred in five of his cases. He now ligatured the internal iliacs in the worst type of case. The speaker commented favourably on the systematic radiation of the pelvis by X rays after local radium applications, but had nothing favourable to say about the use of colloidal preparations. In referring to the Percy cautery operation he said that the average life duration of those who died had been 13·9 months after operation, which compared with 8·9 months in the radium cases after treatment and a total duration of life of 14·8 months in untreated inoperable cases. He had found that post-operative progress with relief of symptoms and absence of shock was a striking phenomenon following the Percy operation. He sometimes employed small doses of radium six to eight weeks afterwards.

Dr. M. Donaldson, in his paper on

Treatment of Inoperable Cancer of the Pelvic Organs,

pointed out the necessity for educating the public on the early symptoms that might point to malignant disease in women. He did not believe this would increase the number of cases of "cancer phobias," but would tend to diminish it. He then described in detail the technique he employed for radium treatment of carcinoma of the cervix, the main principles of which were the use of 20 or more long needles of moderate intensity buried in and around the growth giving a continuous exposure for six days. The results of this technique were more promising than those of the method he had previously employed. He then drew attention to the necessity of investigating the biological laws involved in irradiating living tissues, and stated that interesting work by Dr. T. S. P. Strangeways and his other colleagues was being done on the effect of irradiation of tissue cultures, the results of which emphasised the importance of the distance and time factors. Finally, he pointed out the urgent necessity for organised and coördinated research, and hoped that the profession as a whole would urge the raising of public funds for this purpose.

Discussion.

Mr. Sidney Forsdike drew attention to the type of case where radium was contraindicated. He described the technique he employed and stated that he always removed any necrotic growth with a blunt curette as a preliminary to radium treatment.

Mr. G. I. Strachan (Cardiff) called attention to the risk of applying radium in cases of pyometra.

Circulatory Changes in Normal Pregnancies.

Dr. Dorothy C. Hare (London) read a paper comprising a preliminary report on an investigation of cardio-vascular conditions in normal pregnancy by means of clinical tests. The object of the investigation was to discover if by the methods of clinical examination evidence could be obtained of changes in the pulse-rates, blood-pressures, and response to exercise tests during the course of pregnancy and to relate such changes to the period of pregnancy in which they occurred. A series of observations on 40 pregnant women was made at four-weekly intervals, and the tests applied under uniform conditions; a number of other pregnant cases were examined once and their records included; 50 women medical students also were examined as controls. Other control figures were also obtained from the work of L. D. Cripps. As the report was a preliminary one the results were therefore incomplete. The mean of the figures obtained in each month of pregnancy was charted and the curves compared with the range of figures in the groups of control cases. The results, so far as they went, were remarkable for the high degree of "normality" and "efficiency" shown. The mean pulse-rates lay within or below the control figures.

		Pregnants.		Controls.
Lying pulse-rate	..	83 to 85	......	None.
Sitting "	..	75 " 87	......	77·5 to 88.
Standing "	..	88 " 99	......	90 " 87.

It was only in the fourth month of pregnancy that the rate lay outside the range of the control figures, and there was no marked difference in the last months from the earlier months. A study of individual pulse records showed no general tendency to increase of rate in the later months. The difference between the lying or sitting pulse-rates and the standing rate was generally recognised as a test of the efficiency of the cardio-vascular mechanism in making rapid adjustments to change of position. An increase of 15 beats or less was usually considered a "normal" response. It was found that 88 per cent. of pregnant women gave a "normal" response and that only two abnormal responses occurred in the last two months. Comparison of the sitting and lying pulse-rates of the individual showed little difference on the whole, an increase or slowing of the rate with the change of position being met with in almost equal numbers. An exception to this was found in the eighth month of pregnancy, when the majority of patients have a slower sitting than lying rate. This was probably to be attributed to the position of the uterus in that month causing an embarrassment of the diaphragm and circulation when lying, which was relieved when the patient sat up, with a consequent slowing of the pulse-rate. The response to change of position in the ninth month was reversed. The exercise efficiency test used was an easy one. Patients stepped up and down on to a stool 7 in. high 30 times in 60 seconds. The pulse-rates after the exercise were recorded. A "normal response" might be taken as a return to or below the resting-rate in that time. A larger percentage of "normal responses" was found in the records of the later than in the earlier months. The blood pressures of the patients were recorded in the lying and sitting positions. They were taken by auscultation over the brachial artery, two observers working simultaneously on the two arms, two arm-bands being attached to the same mercury manometer. Several readings were taken in succession. It was found that the pressures, both systolic and diastolic, might be highly variable in the same individual at one sitting. The systolic and diastolic curves in pregnancy showed a mean rather below the control figures, and the actual range of systolic readings was low. The systolic pressures are not higher in the last month than in previous months, but the diastolic pressure showed a tendency to rise, though not above the control figures. The lying systolic pressures ranged from 116 to 109 mm. Hg. No control figures were available. A record of over 140 mm. was found only four times in 191 records. The presence of a persistent high systolic pressure in any case should lead to careful investigation to exclude the presence of any toxic condition.

Friday, July 24th.

The Rôle of Surgery in the Treatment of Backward Displacement of the Uterus.

Miss Frances Ivens (Liverpool) opened a discussion on this subject. She proposed to confine her remarks to the group of cases which she described as the immobile non-adherent backward displacement. In this group were included both retroversion and retroflexion of the uterus. She challenged the statement so often made that backward displacements in single unmarried women caused no symptoms, and if present they were due to a neurosis. She had found a definite pathological condition in a large number of such cases seeking treatment, and when the lesion was remedied the symptoms had disappeared. She entirely disagreed with the view which would treat not the displacement, but only its complications, and thought it was entirely wrong to conceal from the patient the fact that such a condition was present. The speaker had found it extremely difficult to prove the causal relationship of strain to this condition, but undoubtedly retroversion was more common in women engaged in laborious occupations. In these cases it was possible that the malposition was already present, and the strain only exaggerated the condition. She regarded the dorsal decubitus during the puerperium as the most potent cause of backward displacements. In discussing the pathological changes associated with a retro-displacement, Miss Ivens said that these changes depended largely upon congestion and back-pressure due to interference with the venous circulation in the pelvis. Direct pressure upon the rectum by the fundus of the uterus sometimes produced hæmorrhoids. The speaker then dealt with the symptomatology of the condition and quoted illustrative cases of the results obtained by operative treatment. In her opinion there were only two classes of cases where the treatment of backward displacement was non-operative. These two classes were: (1) pregnancy and the puerperium; (2) grave organic disease. The operation she practised was Mayo's modification of the Gilliam operation, and she had performed it on more than 1000 occasions with only 5 deaths. She had been able to trace 200 post-war cases. Of these 58 per cent. were cured of all symptoms, 14·5 per cent. were improved, and 15 5 per cent. no permanent benefit.

Dr. Russell Andrews (London), who followed, agreed that operative treatment was best in the following types of cases: (1) Uterus fixed and retroverted; (2) dyspareunia; (3) childless women with repeated abortions. In the majority of other cases the retroversion could be ignored, and in this category came most, if not all, single women and girls. He refused to believe that a mobile retroverted uterus of normal size could press on the rectum and cause difficult defæcation and piles. The speaker commented on the fact of how practices differed and thought Miss Ivens saw a large number of school girls the ordinary gynæcologist did not see. He had, however, looked after the nurses at the London Hospital for the past 22 years, and during that time had only seen one case of retroversion. He thought that perhaps the preliminary dilatation and curettage had a beneficial effect on a large number of the cases. In referring to the modified Gilliam operation described by Miss Ivens, he stated that he had seen several cases followed by a small sensitive swelling on each side of the scar, which sometimes turned out to be a hernia. He had never made this lateral incision, but had always sutured the round ligaments to the edge of the aponeurosis on the other side, and had never had cause to regret it.

Mr. R. H. Paramore (Rugby) gave an interesting historical survey of the various procedures adopted for retroversion. He said that intra-abdominal pressure maintained the uterus in position and this depended largely on the muscular tone of the abdominal wall. He thought that surgical treatment was of secondary importance and advised the use of an abdominal support.

Prof. W. C. Swayne said that the rôle of surgery in retroversion depended upon the position of the appendages. If symptoms were present there was always some associated pathological lesion. He discussed the functions of the round ligaments, and emphasised the necessity of restoring the anatomical functions of these structures if an operation was performed.

Dr. Farquhar Murray (Newcastle-on-Tyne) warmly endorsed Dr. Russell Andrews's able criticism on the paper. He said that he could not too strongly deprecate the practice of giving nervous young girls minute details about their pelvic organs.

Prof. E. W. Marlow said that in his experience retroversion was fairly common in young girls and unmarried women, but in the majority of these cases there was comparatively little symptomatology. In cases where marked symptoms were present there was always some degree of descent of the uterus, and in these cases it was always necessary to repair the pelvic floor. He did not think that the operation described by Miss Ivens should be called after Mayo for it was only one of the many modifications of Gilliam's operation. He did not agree about the general condemnation of pessaries, which, when fitted properly, were extremely useful.

Dr. Leith Murray said that he very rarely performed an abdominal section for this condition.

Colonel V. B. Green-Armytage (Calcutta) gave an account of his experience of gynæcological practice amongst the women in India. He believed that a large number of operations performed for retroversion were unnecessary. Miss Ivens briefly replied.

Erosion of the Cervix.

Dr. Gilbert I. Strachan then followed with a paper on the pathology and treatment of erosion of the cervix. This was, he said, the most common lesion in the female genital organs and was of special importance and gravity as a precursor of carcinoma. The pathology of the condition was discussed. The main predisposing factors were any breach of continuity in the cervix as occurred in a cervical laceration, or any alteration in the normal acid reaction in the vaginal secretion. Labour was then the usual antecedent condition, although in nulliparæ or virgins it might be congenital or due to lack of resistance to infection. Gonorrhœa might also be causal. The changes produced in erosion were traced and the possible complications mentioned, stress being laid on carcinoma. The best treatment was preventive, by giving plenty of time for cervical dilatation in the first stage of labour. Should laceration occur it should be sutured accurately if it can be seen. In treating the established condition the merits of application of antiseptics, electrical treatment, cauterisation, and vaccines were discussed, and it was concluded that it was only in slight and early cases that cure was likely to be effected. Most cases required operation, and while curettage would improve the endometritis that was often present, scraping with a sharp spoon was necessary for the hard cervix. The most effective form of treatment was found to be removal of the eroded area by the technique of Bonney. In some cases amputation of the cervix was called for, depending upon the amount of tissue to be removed, while in nulliparæ Schröder's operation was often satisfactory. While this line of treatment was radical it was the only way in which satisfactory and rapid cure could be attained, and was also an important preventive to the future development of carcinoma.

SECTION OF OPHTHALMOLOGY.

This Section met on two days, with Mr. W. M. Beaumont in the chair.

Wednesday, July 22nd.

Eye Injuries and Interstitial Keratitis.

Mr. Holmes Spicer, in opening a discussion on this subject, said that in a certain number of cases there appeared to be a connexion between interstitial keratitis and a local injury to the eye. In his experience such injuries had included a foreign body on the cornea, a "spark from the engine," chemical injury from caustic potash, surgical operation, and so forth. In 8 per cent. of the cases collected by him a direct association could be traced. In some cases the stigmata of hereditary syphilis might be absent and the question might become a most important one from the point of view of legal compensation. Harrison Butler had claimed that there was a connexion with injury in 20 per cent. of his cases, but the difference probably depended on the definition of injury. With regard to an injury being the cause of the attack, he asked how the occurrence of interstitial keratitis in the second eye was to be explained. In syphilitic patients operations such as needling and squint operations had not been followed by interstitial keratitis. On the other hand, in two cases, the condition followed very quickly on simple needling. If the organism is present in the eye there will be an attack some time or other, but the possibility of the organism lying latent for many years must not be lost sight of. As to the possibility that the connexion with traumatism was a mere coincidence, he said that if this was the case we might expect to see cases where an injury to one eye was followed by interstitial keratitis in the other. Personally he had never seen such a case, though in the ordinary course of events the second eye was usually attacked subsequently to the injured one. He did not think the diagnosis presented any great difficulty. Typical interstitial keratitis was always syphilitic. Summing up the evidence, his opinion was that interstitial keratitis depended on the presence of the spirochæte inside the eye and its readiness for evolution. Whether or not an injury was capable of precipitating an attack depended entirely on the stage of evolution in which the spirochæte might happen to be.

Mr. N. Bishop Harman said that the important question from the legal point of view was this: Was it possible that whether, in default of any injury in any particular case, the attack of interstitial keratitis might possibly not have occurred. We must, he said, be on our guard, too, with regard to the psychological factor in all compensation cases.

Mr. Cyril Walker referred to pregnancy as a contributory factor. From the many severe and intractable cases he had seen at Bristol he recalled two especially. In one patient, a woman of 28, an attack began during a pregnancy. The second eye remained unaffected until two or three years later during another pregnancy, when that eye too succumbed. He had heard of a case following on an attack of conjunctivitis but had not himself seen one.

Mr. E. J. Primrose (Glasgow) said that in many cases of adult interstitial keratitis the Wassermann reaction might be negative. The diagnosis between syphilitic and tuberculous cases was not always easy. He advocated the arsenical treatment carried out by men who were prepared to use large doses and deal with any emergency that might arise.

Mr. Inglis Pollock laid stress on the urgency of antisyphilitic treatment. In two cases of interstitial keratitis following an injury to the cornea—both of them typically syphilitic—as the result of prompt arsenical treatment the second eye did not become affected.

Mr. A. W. Ormond recalled his experience during the war at a large hospital where many cases of traumatic corneal ulcer were treated. In as many as 10 per cent. of these cases an attack of interstitial keratitis supervened. The diagnosis between syphilitic and tuberculous keratitis was perfectly possible. Treatment was now far more important than it used to be 25 years ago. At that time mercury did not cure. It was different with modern arsenical treatment.

Mr. R. Wallace Henry spoke of a case of interstitial keratitis alleged to be the result of the administration of an anæsthetic.

Dr. de Schweinitz gave it as his opinion that an injury might lower resisting power, but in no other way could cause an attack of interstitial keratitis.

Mr. Bishop Harman read a paper on

Phlyctenular Conjunctivitis and Keratitis.

He said that in a total of 3300 children who had passed through the schools for the blind and the myope classes in London there were 699 whose disability was caused by inflammation of the superficies of the eyes. Of these 367 had suffered from ophthalmia neonatorum, 90 from purulent conjunctivitis of later years, and 242 from phlyctenular keratitis. Of these 242 cases 69 had such badly damaged eyes that they needed to be trained in schools for the blind. The proportion of total blindness in school-children caused by this disease was 3·56 per cent., while if we add to them the number of children with sight so damaged that they had to be educated in the myope classes, the percentage reached 7·3 of all included in the two types of school.

In discussing the ætiology, he said that it was a disease of the poorer classes, being rare in private practice. Comparing two classes of hospital patients, native and Jewish, it was found that phlyctenules were three times as common among natives as among Jews. The only factor accounting for these two contrasts is the food factor. Children of the middle class were well fed, and so were the children of alien Jews on a diet into which oil largely entered. Both these classes escape the ravages of phlyctenular disease. With regard to age incidence, he said that the frequency increased from the second year of life to the fifth, declining in later years. The state of the mouth in poor children of about 5 was apt to be worse than either earlier or later. The initial lesion was more commonly found in the lower and outer section of the limbus. More than half of the cases observed began in this situation or on the cornea adjacent to it. The nerve-supply of this area was derived from the loop formed by a twig from the lacrymal nerve and from the second division of the fifth, so that irritation within the mouth would explain the occurrence and situation of the eruption. The link of connexion with the lacrymal nerve similarly accounted for the profuse lacrymation that occurred. Unbroken phlyctenules were sterile so that it cannot be contended that the disease is due to microbic infection. Unlike contagious forms of conjunctivitis, phlyctenular disease was not specially rife during the spring and summer months, but is fairly evenly distributed throughout the year. The typical phlyctenule had a fluid content. The early investigators who considered it to be of the nature of a blister were right. These points of evidence converged on the general conclusion that the disease was a manifestation of some general disability and not a specific infection of the tissues of the eye.

With regard to the connexion with tuberculosis, the evidence for this, he said, was very slight. Of the 242 cases of phlyctenular disease already referred to, only eight had tuberculous lesions. Of 81 cases seen more recently only one showed any infection with tubercle. The evidence went to show that the primary general condition is not tuberculous, but feebleness due to lack of proper food and perhaps also lack of sun and air.

The prevention of this disease was bound up with the general social betterment of the people. Among factors making for this were the school medical service, by means of which cases requiring general or local treatment were discovered; open-air schools, dental and throat treatment, and the transfer of serious cases to country hospital schools through such an arrangement as there was in London between the County Council and the Metropolitan Asylums Board. Though these measures involved an immediate expense, when the saving in effective citizenship was considered they could not fail to be an ultimate economy.

A Light Recorder.

Mr. Wallace Henry demonstrated an instrument for recording light minimum and *light difference*. It was a somewhat elaborate piece of mechanism, [illegible] by its means he had made this interesting obse[illegible]tion in regard to light adaptation There might [illegible] difference in the two eyes of as much as 50 per [illegible] in the time taken for light adaptation, even in [illegible] with normal light difference and normal [illegible] minimum.

Mr. A. S. Percival referred to his own simple [illegible] device of revolving discs for testing light minimum [illegible] light difference. As an instance of its practical [illegible] he recalled the demonstration of a defective [illegible] minimum in a case of cataract in which he had discouraged operation on the ground that there was a probability of a macular affection. On the patient's subsequent appearance after an operation properly performed elsewhere but resulting in no benefit to the sight, Mr. Percival found his diagnosis confirmed.

Mr. R. Colley showed a case in which, as the result of an accident to a medical man, a piece of glass 7 mm. long could be demonstrated lying behind the lens and apparently doing no harm, the vision remaining at 6/5. Several more or less similar cases had been recorded.

THURSDAY, JULY 23RD.

On the second day Mr. Freeland Fergus opened a discussion on

Ocular Pain.

Two main causes, he said, were: (1) Uncorrected refraction, defects of accommodation, and muscle balance; (2) septic infection. In the first category he placed cases when there is difficulty in retaining parallelism on distant vision owing to a defective power of the external recti. In the latter he included pain following operations due to defective technique. Corneal ulcers were best treated not by atropine and bandaging, but by pilocarpine, frequent douches, and dark glasses.

Mr. Wallace Henry referred to reflex pain from decayed teeth. He remembered a case in which severe pain in the eyes was caused by defæcation. As a douche in operation cases he used 1 : 4000 acriflavine.

Mr. Bishop Harman referred to heat as our most valuable remedy in dealing with ocular pain.

Mr. A. S. Percival referred to the use of dionine.

Dr. Webster Fox pinned his faith to leeches, belladonna, and poppyhead fomentations and salicylates. He spoke favourably of milk injections (3 c.cm. to favour leukocytosis) and daturin instead of atropine.

Mr. Lindsay Rea read a paper on the

Treatment of Ocular Syphilis.

This paper, he said, was a plea for the prompt and energetic treatment of cases whether acquired or congenital. As an example of the former he displayed on the screen photographs of a young man who developed an alarming proptosis while on his honeymoon. The proptosis increased from day to day. It was directly forwards and there was limitation of movements in all directions, diplopia and pain. The pupil reacted to light, but vision was reduced to 5/60, and subsequently the eye became temporarily blind. There was very marked conjunctival œdema. At first one eye only was affected, but in the course of two or three weeks the second eye also became proptosed. Vision rapidly deteriorated in both and the eye first affected became blind. Meantime the Wassermann reaction was found to be strongly positive, and thereupon the patient was put on injections of novarsenobillon, 0·45 g. every fifth day for eight weeks. After two or three injections the proptosis began to diminish and the vision began to improve. Iodide of potash in 25 gr. doses was also given thrice daily and mercurial inunctions. At the end of three months the vision was 0/0 in each eye and the proptosis had entirely disappeared. It was a case of gummatous infiltration of both orbits rapidly responding to treatment.

Turning to congenital cases, Mr. Rea discussed first the diagnosis and then the treatment of interstitial keratitis. In 72 of his cases the Wassermann test was done. Of these cases 04 were new ones, and in every one of them the Wassermann reaction was positive. In eight old cases it was negative, but in five of them where he was able to get an examination of the cerebro-spinal fluid, although the Wassermann was negative, a luetic curve was obtained by Lange's colloid gold test.[1] He had not found a single case of typical interstitial keratitis which was not syphilitic.

In the case of adults he used N.A.B. injections, beginning with 0 3 g. and rising to 0 45 g., or in some cases to 0·0 g. In the case of children under 10 he used just half these doses and withheld mercury during the period of injections. Ten or 12 weekly injections were given, and under this treatment the results obtained were far better than under the old treatment with mercury and iodide of potash. Moreover, in 03 consecutive cases of interstitial keratitis treated with arsenical injections not a single case of deafness had developed. With regard to the duration of treatment with arsenical injections, it varied from four and a half to eight months. In cases where the veins of a child were difficult to find, Mr. Rea recommended the intramuscular injection of sulpharsenol into the buttock—0 cg. weekly.

The value of Lange's colloid gold reaction in establishing the diagnosis of syphilis was shown by a case of retino-choroiditis with negative Wassermann, both of the blood serum and cerebro-spinal fluid. The colloid gold test showed the luetic curve. Treatment with mercury and iodides arrested the disease and vision in one eye rose from 0/24 to 0/0. An interesting observation, in which Dr. Rayner Batten concurred, was that affections confined to the macula were not due to syphilis, although the macula might become affected in generalised syphilitic affections of the retina. In cases of congenital syphilis the Wassermann reaction was misleading. In old cases it may become negative without treatment, whereas in recent cases, in spite of efficient treatment, it might remain positive. If cases of ocular syphilis were treated vigorously with such preparations as novarsenobillon the results, although not dramatic in suddenness, were consistently good.

Mr. A. W. Ormond read a paper on

Visual Hallucinations of the Sane.

In some cases of hemianopia visual hallucinations appeared only in the half field. They depended on visual memories and the faculty of visual memory differed enormously in different people.

Mr. Wallace Henry recalled a case of distressing visual hallucinations in a patient with both eyes excised which was cured by 1 per cent. cocaine applied to the stump of the nerve in the socket.

Mr. J. Burdon-Cooper read a paper on the

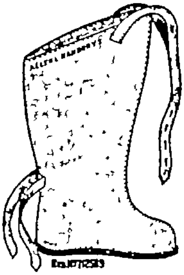
Conservative Treatment of Glaucoma.

Some underlying causes of glaucoma were depression and worry, high blood pressure, errors of metabolism, intestinal troubles, and acidosis. To combat congestive attacks he advocated warm baths, the hypodermic injection of ¼ g. of morphia twice daily, and the administration of nitro-glycerine, ♏i. every four hours, dry heat, scarification of the temple, and pressure massage, which last measure might reduce the tension. These measures were intended not as a substitute for, but as a supplement to operative treatment.

New Inventions.

OPERATING BOOTS.

THE operating boots here illustrated are the outcome of an attempt to obtain a legging which could be worn if desired over outdoor shoes, stand repeated sterilisation by dry or moist heat, be easily kept in place, and wrap up into small compass. The sole of the boot is made of special rubber, which is unaffected by boiling or steam, and the upper is of white coutil, which washes well, and is attached to the sole by hand-sewing, without the use of any rubber solution. The single long tape in front allows the boot to be attached to a front brace button, and the ankle tapes tied over the instep keep the foot portion in place. I have had one pair in constant use at hospital for the last nine months, and they show, as yet, no signs of wear.



I am much indebted to Messrs. Allen and Hanburys, Wigmore-street, W. 1—from whom the boots can now be obtained—for the trouble they have taken in finding the right materials to meet the objects I had in view.

ERIC PEARCE GOULD, M.Ch. Oxf., F.R.C.S. Eng.

Reviews and Notices of Books.

OFFICIAL HISTORY OF THE CANADIAN FORCES IN THE GREAT WAR, 1914–19.

The Medical Services. By Sir ANDREW MACPHAIL, Professor of the History of Medicine, McGill University. Published by authority of the Minister of National Defence. Ottawa: F. A. Acland. 1925. Pp. 428.

A CURIOUS and interesting book; an official history of the medical services of Canada in the war, yet prefaced by an official notice that "the opinions expressed are those of the author himself." The author confides to us some of the difficulties of the Canadian Medical Corps, sometimes caused by "the Imperials," but in the first half of the war the greatest difficulty of all was, he tells us, the Minister of Militia. And no doubt the Minister, like others, was far from perfect; he considered himself a universal expert, misunderstood and misjudged the work of the Medical Corps, naturally embroiled himself with his professional advisers, fought then for himself rather than for the service, and had to resign. Yet it should not be forgotten that "Sam," as he was known all across Canada, had seen the menace of Germany far sooner than most people, had prepared against it with ability, and, in Parliament at Ottawa in 1910, had given publicly to Lord Roberts the credit for foresight which so many smaller people were denying him. He also worked hard to send quickly overseas the 30,000 Canadians of the first contingent.

To the surprise of the War Office "the equipment brought with them was largely worthless and had to be replaced" (p. 29) from British ordnance and medical stores, and their training was still to come; so, though soldiers were badly wanted in France that winter, this division could not be sent across until February, 1915. The author is of opinion they might have been made more quickly battle-worthy in Canada, but in England they were closer to the real school of war, France, and were besides, through that depressing winter, a convincing evidence of the solidarity of the Empire. Once the division did get to France the credit of the Canadian troops was quickly established and soon grew to a great renown, not earned without sacrifice. Of 418,052 Canadians overseas, 51,678 (123 per 1000) were killed or died of wounds, 4960 (12 per 1000) died of disease; a heavy toll of her best which Canada still mourns. The chapters describing personal experiences of various medical officers and units are delightful reading. With his experience of the early confusion and the later orderliness of the war, why did the author not provide an appendix telling the newly volunteered medical officer on what duties to concentrate in the first days of a general mobilisation when all is strange and new, and conservancy and infectious diseases require particular care?

Medical units were, very properly, the earliest to reach the great first Canadian camp, Valcartier, and the subsequent development of the Canadian Medical Corps is carefully recounted and the diseases of the war are discussed. Venereal diseases were a great trouble though not, strictly, diseases of the army, being always contracted from civilians, outside the army. "Idleness is the mother of lechery" is the author's aphorism, from which we may deduce that the best disciplined troops should show a smaller venereal rate. The author agrees with the Official Medical History of the War that it is not yet known whether preventive measures and/or early treatment have really prevented infections from developing, but he reports the experience of the Canadian Corps with some hopefulness. Any man if infected had to disclose where the infection was contracted, and the woman was deported from the area, and, so long as there was no leave, one case only appeared per day among 30,000 men, the usual rate being three or four times as much.

The work must be read as a whole, as its parts are not everywhere consistent. Thus, on p. 306, we are told that "the food at all times was abundant and unfailing," though on p. 296 the food of No. 3 Stationary Hospital at Mudros was stated to have been "scarce and unsuitable for the personnel, impossible for the patients." Marvellous things happen in war, but who would have believed that horse lines, "the best in the army," so Field Marshal Plumer described them (p. 54), were designed by the Mother Superior of a Belgian convent!

CLINICAL THERAPEUTICS.

In two volumes. By ALFRED MARTINET, Paris. Authorised English translation from the second revised and enlarged edition, by LOUIS T. DE M. SAJOUS, Philadelphia. Philadelphia: F. A. Davis Company; London: Stanley Phillips, 45, Brondesbury-road. N.W. 6. 1925. Pp. 718. Price for the two volumes, 67*s*.

THE author in his preface styles his book "a manual of practical medicine, based on an essentially novel plan conforming to the actualities of practice and meeting clinical requirements." He points out that it is a complement to an earlier work entitled "Clinical Diagnosis." It is a bold claim that any book on medical treatment can be essentially novel, but that it conforms to the actualities of practice we are willing to admit. It is wide in its scope and excellent in its material. A medical student cannot possibly, in his short time in the wards, see all the processes used in the treatment of patients. But according to luck, and to a persistence in being present at times apart from the rounds of his chief, he may see many things he would only learn as a resident or not at all.

This book, besides giving many useful helps in drugs, tells in detail how the student must do those things which he has heard of and not seen, or has only seen done by someone else. The first part, the therapeutic agents, is divided into medicinal, alimentary, physical, and psychic agents; medicinal agents are again divided into (1) drugs acting on a definite function, and (2) those acting selectively on infectious and parasitic disorders. This last part, including serum therapy and chemotherapy, forms a section which is especially useful. Drugs acting on organic function are subdivided according to the system of the body in which they act principally and the best known one of each class is taken as a type. Pharmacology and chemical structure is touched on sufficiently to give the raison d'être of many of the drugs.

In the second volume, dealing with symptomatology and treatment, Dr. Martinet lays great stress on the importance of avoiding "equation therapeutics," but gives a very comprehensive 200 pages of common symptoms arranged in alphabetical order, with remarks on the various conditions they may indicate and the appropriate treatment. His fourth section, the treatment of disease, he divides into diseases of the various systems, metabolic, infectious and venereal diseases, skin, ear and eye diseases, and treats their subdivisions in systematic detail. He has made more use of his collaborators here, and whole sections are written by specialists in their particular diseases. The author's article on the treatment of poisoning is very well arranged and employs the tabulated method for quick reference, and his final chapter on instructions to the patient contains a great deal of matter that few general practitioners could read without a certain feeling of shortcoming. He insists that full dietary, hygienic, and physiotherapeutic instructions should be given not only verbally but also "legibly written on good paper"—an excellent rule, if perhaps a counsel of perfection.

Generally, the book is a direct translation from the French. The section on watering places has been liberally adjusted to the American reader, and the writer (or translator) is somewhat unfortunate in selecting Epsom as a place in England known for its purgative mineral waters. The book abounds in long words not in common use in English medicine, of which hypocrinic, crenotherapy, crymotherapy, inoscopy may be taken as samples, and in many respects it is tuned up to the American rather than the English reader. It is a valuable compilation.

THE HEALTH OF CHILDREN.

Health in Childhood. Five Lectures delivered at the Institute of Hygiene. With a Foreword by A. MIDDLETON HEWART, M.D., D.P.H. London: G. Bell and Sons, Ltd. 1925. Pp. 94. 2s. 6d.

Healthy Childhood between Infancy and School Age. By MARY E. WESTON, M.B., B.S. Lond., Assistant School Medical Officer and Assistant Infant Welfare Medical Officer, County of Leicester. London: Faber and Gwyer, Ltd. (The Scientific Press). 1925. Pp. 185. 4s.

IT is a mistake not uncommonly made to assume that one has only to write down the elements of hygiene for children in simple language and any mother will then be able to read, understand, and put these rules into practice. The subject has to be approached and explained in almost as many different ways as there are mothers, so that books on child welfare with an original outlook are still welcome. The first of these two volumes consists of five lectures on somewhat less popular and certainly less known aspects of the subject. Lieut.-Colonel Robert H. Elliot writes with all his well-known authority on the care of the eyes in children; Mr. George Thomson on the care of the primary teeth; Dr. King Brown on the prevention of infectious disease in childhood; the late Mr. Græme Anderson on the prevention of deformities in children; and Dr. C. S. Thomson on the mental and moral education of the child. All these papers, which were lectures delivered this year at the Institute of Hygiene, are of a high standard of excellence and demand the careful attention of all those dealing with the care of the young.

Dr. Mary Weston is concerned with the health of the toddler or pre-school child, a subject about which not much has been written in this country, although, and despite what Dr. Feldman says in his foreword, there have been several excellent volumes published in America. After a brief introduction the author deals successively with the diet, clothing, sleep, physical development, the air and sunshine requirements, the training and the holidays of the child between the period of infancy and school age. Two chapters are added on the child in sickness and on some common diseases. Well written, with much common sense, this book should have a wide appeal.

TOXIC GOITRE.

Kliniske Studier over Thyreotoxicosenes Diagnose og Prognose. By Dr. JOHAN HOLST. Oslo: Jacob Dybwad. 1924. Pp. 96.

WITH the financial assistance of the Fridtjof Nansen Fund, Dr. Holst has published a monograph which embodies his study of 150 cases of Graves's disease or Basedow's disease—terms which he prefers to discard in favour of the more modern expressions thyreotoxicosis or toxic goitre. He attaches a certain value to the Goetsch adrenalin test, Kocher's cytological formula, the blood-corpuscle suspension test, the sugar-tolerance test, and de Quervain's rat test, but it is the basal metabolic rate, as determined by Krogh's method and apparatus, on which he relies most for a diagnosis. He does not, however, undervalue the clinical examination. The term "latent thyreotoxicosis" is used by the author in connexion with those cases in which the metabolic rate is increased, although there are no clinical signs of the disease. It is probable that the patient who suddenly develops Graves's disease after a fright has been for some time suffering from latent thyreotoxicosis. For it is difficult to explain how the organic changes of Graves's disease could develop suddenly as a sequel to psychic shock. As the author points out, a knowledge of latent thyreotoxicosis is of great importance to the early diagnosis and treatment of the case.

Dr. Holst gives an interesting account of cases of monosymptomatic thyreotoxicosis, the patient suffering from neurasthenic symptoms only, or only eye symptoms or diarrhœa. Or the only symptoms may be referred to the heart. It is in such cases that the clinical diagnosis is apt to be wrong, and the determination of the basal metabolic rate is of unusually great importance. It is also very helpful in distinguishing between neuroses and thyreotoxicosis, for if the metabolic rate is found to be normal the patient is certainly not suffering from hyper-function of the thyroid gland. But if there is an increase of the metabolic rate by 25 to 30 per cent., thyreotoxicosis probably exists, although in neuroses also there may sometimes be a slight rise of the metabolic rate. With regard to operative treatment, the author is in favour of early radical resections in order that the proliferation of the toxic cells may be arrested before irreparable damage has been done to the heart or other organs. When symptoms persist after an operation, a determination of the metabolic rate will show whether they are due to an insufficient removal of diseased thyroid tissue or to secondary lesions in other organs, and thus the metabolic rate helps the surgeon to decide for or against another operation. It is again the metabolic rate by which the surgeon should be guided in the worst cases, and when this rate is more than plus 70 per cent. the author considers surgical treatment as dangerous.

The chief message, then, of Dr. Holst's admirable monograph is the value of the metabolic rate to the study of almost every aspect of Graves's disease.

PRACTICAL PATHOLOGY.

Including Morbid Anatomy and Post-mortem Technique. Second edition. By JAMES MILLER, M.D., D.Sc., Professor of Pathology, Queen's University, Kingston, Canada. London: A. and C. Black. 1923. With 100 figures. Pp. 528. 15s.

WE do not wonder that a second edition of this book, first published in 1918, has been called for. It does what it sets out to do very well, and gives a plain, easy, straightforward account of what the elementary student of pathology wants to know about his work in the post-mortem room. Eminently practical directions for making autopsies are interspersed with brief descriptions of morbid appearances and their meaning, and at the end a section is devoted to the methods of preserving and examining tissues. Prof. Miller gives one good way of doing each thing, which is educationally a far sounder plan than providing a maze of alternatives. It is certainly better to be able to cut up a body and display the organs neatly according to some definite and familiar plan and to be able to stain a section really well with hæmatoxylin and eosin than to half know three ways of performing a necropsy and ten ways of staining a section. There are, of course, plenty of small points in which each working pathologist who reads the book will be sure that the method recommended is not really the best—it is cosmetically preferable to open the neck by two incisions from the mastoid processes meeting at the top of the sternum than by a single median cut (Fig. 4); it is more elegant in v. Kossa's method (p. 431) to develop the silver phosphate with pyro than to rely on sunlight; rubber gloves are handier in use if one wears a pair of thin cotton gloves over them (p. 5); there is more to say about the ætiology of rickets than is found on p. 326—but there will be plenty of time for the student to learn some of these variants when he has really mastered some one way of doing what is requisite and necessary.

Industrial Poisons in the United States.

By Alice Hamilton, M.D. New York: Macmillan Company. 1925. Pp. 590. 21*s*.

The writer of this volume is an international authority who has made the matters discussed her own speciality and has visited many countries in the course of her studies. In some ways the title chosen is somewhat misleading, since, although the objective is industrial poisons in America, the information amassed is drawn to no small extent from investigations made in Europe and particularly in Great Britain. The scope of the book is strictly limited to recognised industrial poisons, such as lead, mercury, arsenic, caustics, acids, vapours and gases, and benzene compounds; but what determined the inclusion of troubles from oil and tar cancer, while the toxic silica is omitted, is difficult to guess. Further, there is no reference to caisson disease, which is well known in the United States, and might usefully have been grouped with gassing. If limitation of space was the determining factor, condensation might have been exerted relative to lead poisoning, which receives the lion's share of space; indeed, it accounts for nearly half the volume. Lead poisoning has in the past truly led the way in industrial toxicology, but its causation is now so well understood and its frequency is so rapidly diminishing, that the time has come to place it in more correct perspective. Nevertheless, the exposition given is likely to become for some time the standard for reference.

The scheme adopted is to state for each poison first a description of its symptoms and pathology, and then of the risks as they occur in industry. Long technical explanations of processes—all too common in books on this subject—are commendably avoided; and chemical questions are only introduced when required to display a connexion between molecular structure and toxicity. Prevention of risk is only incidentally discussed in connexion with causation, while treatment is entirely omitted. This omission, particularly in regard to such things as gassing with carbon monoxide, seems unfortunate.

On the whole, the book is readable and well-written. It places at the disposal of those interested a wealth of information in ordered sequence.

Electrical Conductivity of the Human Body.

La Conductibilité Électrique du Corps Humain. By André Strohl, Docteur-ès-sciences, Professeur à la Faculté de Médecine d'Alger. Paris: Masson et Cie. 1925. Pp. 128. Fr.8.

Dr. Strohl has conducted original research on the electrical conductivity of the human body. By means of a ballistic galvanometer he has been able to determine the resistance of the tissues at the moment when the current commences to flow and for minute fractions of a second after. With the apparatus at their disposal, previous workers have not determined the resistance at such early periods of the flow of the current. When a current at constant voltage is used, Dr. Strohl has shown that the resistance of the body rises, during the first few thousandths of a second, to a value two to five times greater than that found when the current has passed for longer periods. After this initial increase it falls, at first quickly, and then more slowly, till it reaches the values obtained by earlier workers. The author regards this initial rise, the existence of which has not hitherto been known, as the result of an E.M.F. acting in a direction opposite to that of the measuring current and produced by polarisation. This polarisation increases at the moment when the current commences but then diminishes slowly. It takes place throughout the tissues traversed by the current, but mainly in the skin. It is determined by the varying permeability of the cell membranes to the tissue-ions and it disappears, in part at any rate, when the integrity of the membranes is lost. The author thinks that the degree of permeability depends upon the nervous system, probably the sympathetic.

Dr. Strohl's work is of high scientific value. It shows that the polarisation of the tissues, causing as it does considerable variations in the strength of the current produced by a constant E.M.F., constitutes a source of difficulty in the measurement of tissue excitability to currents of short duration, and a possibility of error in the determination of the chronaxie. The author thinks that further study of the opposing E.M.F. caused by the polarisation, and the initial resistance of the tissues would yield information of value in the study of certain functions of the tissues.

Alcohol in Medical Practice.

By Courtenay C. Weeks, M.R.C.S., L.R.C.P. London: H. K. Lewis and Co., Ltd. 1925. Pp. 186. 3*s*. 6*d*.

The object of this little book is to show that although there has been a remarkable decrease in the use of wines and spirits in various hospitals and institutions within recent years, there is still room for even further decrease, if the use of alcohol as a drug be removed from the realm of empiricism and treated scientifically on its pharmacological merits. Dr. Weeks claims that his conclusions have been reached by a "careful consideration and appropriation of much that has been written during the past thirty years." These conclusions would carry more conviction to his professional brethren if some of the rhetorical utterances, which the author no doubt has found useful in public lectures, were curtailed, for they obscure a scientific analysis of the subject. Nevertheless, many of the arguments are very sound, and the tabulated results of an inquiry into the comparative amounts of alcohol used in various hospitals and other institutions in the years 1900 and 1923 are very instructive. One point, and not an unimportant one, which Dr. Weeks ignores, is the undoubted psychological effect of alcohol taken in even small doses by patients in the belief, *erroneous or otherwise*, that it is doing them good. A chapter on the evolution of medical opinion has been added and is very interesting reading. Dr. Weeks writes well and in a convincing manner, and perhaps this volume will be of some assistance in enabling those of "our professional brethren who have been so fast bound in the shackles of the past to emancipate themselves and their patients into the greater freedom of a newer knowledge." But this is one of the passages which the book would be better without.

Anatomische Praeparieruebungen.

By Hans Virchow. Curs I. and II. Berlin and Leipzig: Walter de Gruyter and Co. 1924. Pp. 66 and 110. M.5.50.

This is a guide for anatomical students, telling them shortly what they are expected to display, but not saying much on the subject of carrying out the intention. The first "Curs" is concerned with the muscles only, and the arm takes seven pages in this connexion. The fullness, comparatively, of the sections on the post-vertebral muscles seems to us rather remarkable, for one would imagine it more profitable to expend effort so relatively great on more worthy subjects; moreover, these muscles are among the easiest to teach in the body. Similar remarks might be made on the treatment of the face. These little books are not for teaching anatomy but for guiding the learner, but even from this point of view they are the curtest with which we are acquainted, though little human touches appear here and there among the short directions which may give pleasure to a worried reader. There are simple diagrams to show incisions and broad margins and spare pages for notes. The printing and appearance of the book are excellent.

This simple treatment gives relief from pain in Entero-colitis

In Entero-colitis, where there is pronounced muscular rigidity and pain, an application of Antiphlogistine applied hot and thick over the entire abdominal wall, not only relieves the pain, but proves a valuable adjuvant to internal medication.

The sustained heat of Antiphlogistine produces a depletion of the enteric and peritoneal vessels and stimulates the solar and hypogastric plexuses.

In Entero-colitis, or any affection involving deep-seated structures, the *genuine* Antiphlogistine, by its peculiar property of maintaining a uniform degree of heat upwards to 24 hours, stimulates the cutaneous reflexes, causing a contraction of the deep-seated, and coincidently, a dilation of the superficial, blood-vessels.

Over 100,000 Physicians use the *genuine* Antiphlogistine—it is the world's most extensively used ethical proprietary.

The Denver Chemical Mfg. Company

'BYNIN' AMARA

Trade Mark

A Powerful Tonic and Hæmatinic

'BYNIN' AMARA is of special value in neurasthenia, particularly when associated with low blood pressure, anæmia and atonic dyspepsia; in convalescence it gives that impetus which often enables the system to overcome the aftermath of disease and to recover completely.

'Bynin' Amara has important advantages over Easton's Syrup on account of its basis being 'Bynin' Liquid Malt in the place of syrup. The 'Bynin' Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

COMPOSITION

Quinine Phosphate - -	1½ gr.
Iron Phosphate - - -	2 „
Nux Vomica Alkaloids	
equal to Strychnine	$\frac{1}{16}$ „
'Bynin' Liquid Malt - -	1 oz.

DOSE: 2 to 4 fluid drachms in water twice or thrice daily after meals.

Further particulars and free sample will be sent on request.

AN IDEALIST ON MODERN SCIENCE.

The British Association for the Advancement of Science held its annual meeting at Southampton last week, and on August 26th Prof. Horace Lamb, F.R.S., delivered his presidential address. As a mathematician, he confessed that he found it difficult to choose a subject in which he had himself been interested without overstraining the patience of his audience, but he was equal to the test. He spoke on geophysics, a subject of intense interest to everyone of whatever education, and confined himself to facts of the earth's constitution that have been gathered from observations made in our own time, and mainly those that bear a mathematical or physical significance. Before he came to the subject-matter of his address, however, he reminded the Association of some general truths concerning science that cannot be repeated too often. He said that to the question "What is the real purpose of science, and what is the common inspiration of scientific effort and the common ambition of scientific workers?" there is a kind of stereotyped official answer, given in a formula that has become almost consecrated—viz., "To subdue the forces of Nature to the service of man." In other words, the only real value of science is as a key to the material gains and the larger powers that have in the last two centuries so transformed the external part of our lives, and since there is no knowing what abstract research may not prove in the future to promote the supreme end, the more speculative branches of science are to be not only tolerated, but to a certain extent encouraged. Now this Prof. Lamb rightly held to be only a part of the truth. Practical utility has undoubtedly been the conscious aim of much scientific work, and sometimes perhaps its main justification, but the Association would not admit that this formula adequately described what had really inspired discovery through the ages. The conic sections of Apollonius were to him not a possible future guide to the motions of planets, but a study that was legitimate and respectable in itself; and Faraday and Maxwell, feeling their way towards an electric theory of light, had no prescience of wireless telegraphy, though this was a development of their researches by no means remote.

For the British Association the primary aim of science must be to explore the facts of Nature, to ascertain their mutual relations and to arrange them as far as possible into a consistent and intelligible scheme. This is the true inspiration of scientific work, as success in it is the appropriate reward. The material effects come later if at all, and often by a very indirect path. In this constructive task, the President saw a very distinct æsthetic motive, and he showed in a fascinating piece of argument that the research worker was really as much an artist as the musician or the sculptor. A well-ordered piece of algebraic analysis is very like a musical composition. To the uninitiated it is merely a mass of curious symbols, but so is the score of a symphony, and in both is shown that purposeful evolution of a mass of unrelated elements into a grand harmonious unity, that marks the working of the universal creative life. Enthusiasts are using a perfectly true analogy when they speak of the poetical charm of Lagrange's work or the classic perfection of Maxwell's expositions, and the interest men find in the latest achievements of physical science should be not so much due to the hope of future profit as to the intrinsic beauty and novelty of the visions unfolded. Nevertheless, it would be disloyal to science, said Prof. Lamb, to depreciate the material advantages that it has bestowed on civilisation. The most utilitarian result is based on long and patient study and experiment, and science is also greatly indebted to industry for the impulse it receives from new problems and the extended scope that industry opens for its experiments. The National Physical Laboratory, started mainly in the interests of industry, is now, as Prof. Lamb pointed out, a great institute of theoretical as well as applied science, informed throughout by the true spirit of research. In speaking of Huxley in connexion with the increased intellectual freedom of to-day, the orator defended science against the criticism that arose from the disappointment of those expecting it to reform human nature, a criticism that President Wilson has expressed forcibly by the words, "Science has won us great liberty in the physical world but has not freed us from ourselves." It is not in the province of science to improve human nature. Science can give the gifts, but cannot bear the responsibility for their use by the human race. It can take its rightful place in our sports, as Prof. A. V. Hill shows well in his address to the Physiological Section of the Association (see p. 481), but it cannot prevent the abuses of too much play. Medical science has given us longer and healthier lives, but is not responsible for the use we make of them. It benefits both the just and the unjust, but we would not on that account close our hospitals or condemn our doctors.

Prof. Lamb then set forth some very interesting facts about geodesy, and the results of the latest researches on the shape and constitution of the earth, its rigidity and elasticity, and the forces that act upon it, and closed on a note of tribute to the great part that local universities and university colleges have played during the last 50 years in developing science in this country and the empire. He referred to the new schemes by which the University College of Southampton were now increasing their activity and furthering their development, and wished them every prosperity in the name of the British Association. Science has never been so widely and so enthusiastically cultivated as at the present time, with so complete sincerity, with more brilliant success or even with less of international jealousy: Prof. Lamb's words to this effect can fairly be re-echoed by those who pursue medicine.

THE INDIAN MEDICAL SERVICE.

Last week, in the Students' Number, we essayed to place before the medical schools a picture of the Indian Medical Service which would enable those who were choosing a career, and their advisers, to judge what the opportunities really are in the Service—both what are the drawbacks which have ensued on the great political changes of recent times, and what are the advantages which may be secured to the members of the Service under the various schemes put forward to deal with an admittedly difficult situation. How difficult was well elicited recently in the House of Lords when Lord Sydenham asked the Secretary of

State for India "whether measures are in contemplation adequately to fulfil the medical requirements of the Indian Army, British residents, official and non-official, and the civil hospitals, and to secure the progress of modern science in all its branches throughout India." In support of his inquiry Lord SYDENHAM reviewed briefly but eloquently the magnificent work that has been done for many years by the Indian Medical Service; he did not say a word too much when he claimed for it the position in the past of the finest public medical service ever created. The justification of this praise is to be found not only in the standard of health which has always been maintained in the Indian Army to which the Service specially ministers, but in its achievements on the civil side whereby a hospital system has been spread over the Indian Empire, and a directive force produced for the support of all that may be called sanitation in the country. When statements like these can be made unchallenged—and identical sentiments have been appearing in our columns for the last three-quarters of a century—no one can look upon a complete revolution of such activities with anything but sincere regret. But the idleness of tears is well replaced by constructive energy for the future. India definitely requires European medical assistance, not only for the care of the military and civil European populations, but for the maintenance in the country of that spirit of modern medicine which has accomplished already such mighty things, and which day by day is spreading in influence and value. It is a national responsibility to meet the requirements.

We need not recapitulate here the recommendations, now some eight years old, of the Royal Commission on the Public Services, nor those of the Verney Lovett report, for they have all been thoroughly discussed. The practical point is how far the last concessions under the recommendations of the Lee Commission will offer attractive terms for young medical officers and will at the same time provide in India for the three things which are seen to be essential—namely, the maintenance in India of modern standards of medicine, the conservation of the health of the military and civil Europeans, and the due care of their families resident in India. The answer to this far-ranging question was to some extent supplied by the Secretary of State for India in his reply in the House of Lords to Lord SYDENHAM'S request for information. The Lee Commission, Lord BIRKENHEAD explained, had taken the same line with the Indian Medical Service as with the other All-India services in dealing with what are termed the "transferred subjects." By the Commission it was proposed that the R.A.M.C. should absorb the I.M.S., but the conclusion has since been reached that the I.M.S. ought to remain as a military service, its reserve being secured from the officers lent to the civil administration. The recommendations further proposed that the Provincial Governments in India should in the future recruit and control the services for whose work they were responsible to their legislatures; but here the Secretary of State pointed out that in the case of the Indian Medical Service the general principle is limited by the considerations that the needs of the Army would have to be met by drafts from the Civil Medical Service—a service 50 per cent. Indian recruited—while special arrangements would be made to obtain medical attendance for European residents by British medical men. But efficiency in such attendance may be difficult to secure, and there does not seem any stronger appeal inherent in the work than we have been able to put forward last week. Good men will make their presence felt and appreciated, but unless the districts are limited there is much chance of wasted effort. Lord BIRKENHEAD inclined to the belief that it will be essential to earmark for the portion of the Army Reserve lent to the civil side, but not required directly for the medical care of the British Services, a number of civil positions, and he instanced research or professorial appointments. These appointments have always been attractive to officers of the Service, and, said Lord BIRKENHEAD, "if the essential Army Reserve maintained in civil employment allows a margin (as it almost certainly will) it is clearly a gain not only from the point of view of recruiting inducements, but to Indian public health generally that the men should be employed in the departments of research and teaching in which their predecessors have done so much for the welfare of India."

At any rate the period of inactive regret seems to have passed, and a general conclusion reached that there is a fine future before the Indian Medical Service, even though vast alterations in the world, mainly of modern origin, have brought with them a revolution in the conditions of work. Those who enter the Service now, no less than the pioneers of medicine in India a century and more ago, will have before them a great constructive task. Their predecessors tilled virgin soil. The present soil, though much remains untouched, has in the great essentials been cultivated and cultivated successfully, but under methods which in detail will no longer be pursued. Success will none the less come to the Service while its great ideal remains of promoting in India, for Europeans and Indians alike, the principles of health and sanitation. Medical science should know no difference between races, but it cannot, out of unbounded tolerance, be called upon to countenance mysticisms and superstitions. The work of the vaids and hakims, and the antique theories of indigenous medicine will give place in time to scientific procedures founded upon anatomy and physiology, upon observation, experiment, and research. Much tact will be required to persuade many millions of uneducated persons to look to science for their salvation, and the early energies of the Indian Medical Service in the future may have to be devoted, apart from their definitely official duties, to the education of the community through qualified Indian doctors.

THE RECOVERY OF THE LONDON HOSPITALS.

THERE is much that is comforting and encouraging in the annual report of King Edward's Fund upon the work and finances of the 118 London hospitals during 1924 which has just been issued. Not the least significant of its masses of figures are those which show that the number of beds has grown by 350 during the 12 months—practically a new bed every day—and that the number available in London is 1620 more than in the year before the war. With the very recent report of the Voluntary Hospitals Commission on bed capacity before us, it is obvious that the accommodation is still much too small, but so substantial a growth in a single year is a remarkable indication of the resiliency of the voluntary system. Income has kept pace with expenditure in an almost exact ratio —both are, roughly, double what they were in 1913. When, however, we compare 1924 with 1923 we find that maintenance expenditure has gone up £123,000 whereas income has increased by less than half that amount. Nevertheless, the aggregate deficits of 1920, 1921, and 1922 have, during the last two years, been changed into aggregate surpluses, and the number of hospitals with deficits fell from 77 in 1920 to 51 in 1924. That is still far too many, yet if the present rate of progress can be continued, in another few years minus quantities will be almost unknown in London hospital finance. The need of money for building, equipment, and endowment remains, and is likely long to remain, very serious, but here again the prospect is distinctly encouraging. During the last three years not far short of a million and a half has been given for these purposes.

Voluntary gifts are still the rock upon which hospital expenditure is based, and it must necessarily always be so. These gifts last year provided 37 per cent. of the aggregate income, but they are now being run rather closely by patients' payments, which in 1924 reached 29 per cent. of the receipts. This is a figure that is ever growing all over the country, and the more it grows the stronger the voluntary position will become. It is hopeless to expect that great hospitals can "live on their means," and last year their investment income was only one-fifth of the total. Ten years hence the demand upon the resources of the hospitals will be even heavier than at present. It is therefore important to consider the possibilities of reducing expenditure in directions that will not impair their usefulness, and Sir Mackenzie Chalmers has just renewed the suggestion to which we gave support a few months ago, that they should be relieved of a proportion of the heavy burden of local rates. It is understood that the London hospitals pay close upon £10,000 a year in rates, and there is a strong claim for their all-round reduction by, say, one-half—since they clearly derive benefit from local expenditure the case for total exemption would not be strong. Then there is the old story of the death duties on bequests to hospitals—duties which not only rob the hospitals but discourage testators, since both the institution and the dead man's estate suffer. Lord Cave's Committee some four years ago recommended that bequests to hospitals should be exempt from the 10 per cent. legacy duty on the ground that "there appears to be no good reason why the State should intercept at the source one-tenth of all sums bequeathed for the benefit of the sick." Since then more than one Chancellor of the Exchequer has refused to honour a recommendation which, it is believed, would help the hospitals to the extent of about £100,000 a year without raising any of the thorny questions implicit in more direct forms of State aid.

◆

THE INTERNATIONAL CONGRESS ON CHILD WELFARE.

THE first International Congress on Child Welfare has been held during the past week in Geneva, and the various factors in the well-being of the young have been taken into consideration from international aspects. With regard to the diminishing of infant mortality, some of these may well be beyond human power; for example, Dr. Afifi, speaking as an official delegate of the Egyptian Government, stated that the excessive heat of the summer in Egypt was responsible to a large extent for the increased mortality of infants during the months of June, July, and August. The infant mortality in Egypt is certainly very high, for the last figure which we have seen was 143 per 1000 births; but before the sacrifice of life thus implied can be attributed to the climate it is necessary that we should have analogous figures for comparison collected from other countries having as wide a range of temperature as prevails in Egypt. The season of the year when the deaths occur is another point which might well have been brought before the Congress, and no doubt in future meetings subjects like this, of wide international relevance, will be set down for discussion. According to Dr. Afifi it is noticeable that in Egypt the infant death-rate per 1000 has gone up steadily for some years, almost in proportion to the increase of the population, which is simply a proof of his own statement that it is the conditions prevalent in the cities which are responsible for the sacrifice of child life.

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF SURGEONS IN IRELAND.

A RESOLUTION was unanimously adopted at a special meeting of the Council of the Royal College of Surgeons in Ireland, expressing high appreciation of the conduct of Mr. R. C. B. Maunsell, the President, in the recent controversy, and confidence of his defence of the interests of the College. The Council then considered the whole situation, which has arisen under the decision to institute a separate medical register for the Irish Free State, taking note of many suggestions from various sources that they should intervene in the political issues. The Council, however, decided, seeing that the medical profession in Ireland have never interfered in any way in politics, to fight the matter by educating public opinion, and only thus influencing politicians. As a beginning of the education of the public they have decided to convene a meeting of medical practitioners on Sept. 8th in the Examination Hall of the College.

OCCUPATIONAL DISEASES OF SEAMEN.

Dr. H. Ruge, Marinestabsarzt (Surgeon Lieut.-Commander) in the German Navy, in some interesting articles published in the *Marine Rundschau*, observes that when diseases of seamen came prominently into notice in the age of the great voyages of discovery the first and worst was scurvy. Next in importance were the infective diseases: Typhus (ship-fever), typhoid, dysentery, and in the tropics yellow fever and malaria. The number of sick was almost incredible in these early expeditions. In 1757 a French expedition, as it sailed, sent 400 typhus cases ashore at Brest from two of its ships. A thousand were landed at Louisburg on arrival, survivors were re-embarked in autumn, and when the ships reached Brest there were 4000 sick in the fleet, while hundreds had died during the passage. Hosier in 1726, off Colon, lost his personnel twice over from yellow fever. Little was known definitely about prevention, but Cook (1772–5) and La Perouse (1785–8) had hardly a man sick in their voyages. The food was unbelievably bad; the water was no better. It was not till 1815 that iron tanks began to replace the old decaying wooden casks. To make the dirty, stinking water tolerable it was mixed with rum, of which each man was issued with 5 oz. daily. Thereon alcoholism began to rage. Rouppe (1701) calls delirium tremens the characteristic disease of seamen, but improvement set in in the latter half of last century, and the disease is now rare.

Dr. Ruge classifies the sickness of the modern German Navy in four main groups: Chills, mechanical injuries, inflammations of connective tissue, and venereal disease. Under "chills" are included tonsillitis, sore-throat, bronchial catarrh, pleurisy, acute catarrhal, gastric and intestinal attacks, and rheumatism of muscles or joints. Chills are more common afloat than ashore (as 75 to 65), more frequent in iron than in wooden ships (as 3 to 2 in 1893–7), and it is the engine-room, or rather the stokehold, staff that suffer most, and he comments that these men should always wear jerseys when on deck in cold weather; steam heating of the ship also lessens risk. Mechanical injuries cause much loss of time. They are more frequent and more dangerous in sailing ships, but these ships are becoming few. The mortality of accidents in sailing ships is 30 per cent., in steamships 5 per cent. But most accidents nowadays occur about the guns, and sailors are the victims; there are few accidents in the engine-room. Recruits and men new to the ship suffer most, and accidents are more frequent on Mondays, lessening as the week goes on. This is due to unwisely-spent leave at week-ends, when, too, venereal disease is most often acquired. Eighty-five per cent. of accidents occur on duty. Many might be prevented by improved construction of ships, but accidents there will always be where people are working hard. Men in ships are fortunate in having a doctor at hand when they are injured, so that wounds need not become septic. Boils cause much loss of service; they are generally on the arms, and attack sailors more than stokers. They are at their maximum in summer but have a second maximum in autumn, when the recruits join. The recruits are very susceptible, probably because they are constipated. Cleanliness is the best protection against boils, and once they have a hold on the ship, the ship should be disinfected. Three-quarters of the venereal infections are contracted by men under the influence of alcohol. At Hamburg, Nocht found 7000 cases of venereal disease in three years aboard ships entering the port. The East Asiatic Squadron has had one-third of its force at one time under treatment. Sailors suffer much from syphilis, and the worst infected women are at the ports. Unlike alcoholism, venereal disease has decreased little since the war. The men in the German Navy are warned, preventives are always available for them: the merchant seaman is less protected. Dr. Ruge's article deals interestingly with a subject too little discussed.

PYELITIS IN INFANTS.

CASES of pyrexia occurring in infants of a few days or a few weeks old are frequently difficult to diagnose and troublesome to treat. They may, and usually do, have most symptoms referable to the alimentary tract such as anorexia, loss of weight, and vomiting. The fever or other manifestations of general constitutional disturbance may persist in an exasperating way for weeks and finally clear up without any diagnosis having been made, or any treatment, except "symptomatic," having been suggested. Some light has been shed on the possible cause of many of these cases in a discussion led by Dr. L. W. Sauer, of Evanston, Illinois, before the recent American Medical Association Session at Atlantic City.[1] He quotes 12 cases of his own, and three of Helmholz, in which the infants, varying from 6 to 28 days old at the probable onset of the disease, suffered from pyelitis; and he arrives at the following conclusions: (1) Neonatal pyelitis is probably a periodic disease occurring more frequently in male infants. (2) Gastro-intestinal symptoms, especially vomiting, anorexia, diarrhœa, and tympanites predominate. (Other of the more common clinical features noted are pyrexia, loss of weight, pallor, and constipation.) (3) The urine is invariably strongly acid and contains pus, *B. coli*, and a variable amount of albumin. Under the low-power lens numerous polymorphonuclear leucocytes, epithelial cells, erythrocytes, and perhaps casts are seen even in uncentrifugalised urine when fresh. (4) The disease, when free from complications, usually responds within six weeks to diuresis and continued alkalinisation of the urine. (5) The infection is probably by way of the blood-stream, the organism being pathogenic enteral *B. coli*. Diagnosis is not easy in the early stages, for various reasons, and it may be difficult in private practice to obtain a sample of the urine. Also it is known that while the pyrexia lasts there may be only one or two pus cells in the urine—scarcely sufficient to establish a diagnosis—and only when the temperature is nearing normal may there be an outpouring of sufficient pus to make the condition easily recognisable by microscopic examination. This raises the question as to whether the condition may be primarily and not secondarily a colon infection, especially as the symptoms are referable to the alimentary tract before pyuria is present. Alkalies are recommended in the treatment of such cases, though doubt has been cast on whether they are valuable in themselves or only in so far as they promote diuresis. Certainly the abundant use of plain water is advisable. Other measures suggested are careful regulation of the milk or other food, the administration of hexamine, and, in cases of extreme anorexia and vomiting, occasional stomach lavage, subcutaneous salines, and rectal feeding. It is possibly advisable to continue the administration of alkalies for several weeks after the urine is free from pus, albumin, and bacilli. In cases of troublesome diarrhœa the treatment of acute enteritis should be followed—e.g., castor oil, starvation for 24 hours, sips of sterile water, and a few minims of brandy alone being given; then albumin water, chicken tea, and so forth, until it is considered safe to begin with very dilute milk or other food of low carbohydrate content. The prognosis is good. Thirteen of the 15 cases quoted by Dr. Sauer recovered. Of the two exceptions, one was complicated by meningitis, and the other by congenital stenosis of the right ureter, with multiple abscesses of both kidneys, and *B. coli* septicæmia. Finkelstein, in 1924, reported that he had frequently diagnosed pyelitis within the first two weeks of life. Apart from his work and that of Helmholz there is little literature on the subject, but the condition is probably much more common, in milder degrees at any rate, than is generally supposed. Certainly it is possible that many cases of pyrexia in infants, which clear up in a most gratifying way when a mixture containing a little sodium bicarbonate and flavouring matter is administered, may be due to pyelitis.

QUINIDINE IN MALARIA.

A RECENT publication of the United States Public Health Service[1] shows that the death-rate from malaria from 1919–23 still ranges as high as 40 and 50 per hundred thousand in some of the Southern States, although there is encouraging evidence that the disease is gradually disappearing and constantly becoming confined within narrower geographic limits. Some years ago a committee was appointed by the Medical Research Council to inquire into the value of quinine derivatives. The reputed toxicity of cinchonine and the previous reports of Major H. W. Acton, I.M.S., on the value of quinidine decided the committee to confine its inquiry to the properties of the latter alkaloid. Naturally, the conduct of this investigation was beset with many difficulties. Since the committee had no long series of malarial patients in a malaria-free country on which to experiment, the test took the form of a comparison of the relative efficacy of quinine and quinidine in causing disappearance of the parasites from the blood during an acute attack, and were carried out by medical officers in various centres.[2] Reports have been received from Palestine, Khartoum, British Guiana, Uganda, and the Federated Malay States, and all suggest that quinidine is at least as efficacious as quinine, but do not support Major Acton's original suggestion that quinine is definitely inferior to quinidine in the benign tertian infection, though specific for the malignant subtertian parasite. The contribution thus made is a small one, but should lead on to further and extensive observations. It deposes quinine from the position of unique value which practice and tradition have accorded to it among the cinchona alkaloids. The depressant effect of quinidine on the heart may constitute a real drawback to its employment, but the committee have reason to think that the reputed toxicity of cinchonine is due to impure specimens, and a small supply of carefully purified cinchonine has been sent out for trial at Kuala Lumpur. A systematic comparison of these alkaloids, particularly cinchonine and cinchonidine, is very much to be desired. If the suggestions made in this preliminary report are confirmed, it will form a most valuable contribution to medical science, for if an indefinite mixture of the alkaloids could replace quinine the problem of cheapening the supply of antimalarial remedies would be much simplified. Interest in the experiments is not confined to malaria-infested countries, since the efficient control of benign tertian malaria is of great importance to British psychiatrists in connexion with the treatment of general paralysis by the Wagner-Jauregg method.[1]

INOCULATION AGAINST MEASLES.

Dr. Arturo Atria, of Santiago de Chile, has writen a book[2] advocating the universal adoption of the practice of inoculation against measles. As physician-in-chief of the Section of Bacteriology at Santiago and a late student of the Pasteur Institute he speaks with a certain authority, and he invokes the support of tradition by giving considerable space to enthusiastic eulogy of Home, a Scottish physician of the eighteenth century, who first experimented with inoculation about 1740 on a small scale. Home was certainly an able man, much in advance of his age, but the number of his cases was far too small to admit of any deduction being made from the results, and his work is only of historical interest. Nor does the amount of work done since on the same lines come anywhere near to justifying the sweeping conclusions arrived at by Dr. Atria. His attitude may be judged of from the fact that he speaks of 1150 cases as being a colossal number, whereas to arrive at any definite judgment we should need thousands of cases, carefully observed during a period of years. No evidence is offered as to how long the effects of inoculation last in conferring immunity, nor does the author seem to weigh the very varying degrees of liability in communities and individuals in considering such statistics as he has got. Dr. Atria advocates wholesale case-to-case inoculation with the blood of individuals at a certain stage in the disease, but he does not face adequately the difficulties and dangers of the course that he proposes. Two obvious ones may be mentioned: (1) As the virus cannot be stored, large numbers of cases would be required from which to inoculate, and there would be a constant risk of imparting some other disease, such as syphilis or tubercle. (2) As the constitutional reaction in effective cases is presumably more severe than in ordinary vaccination, very large provision would have to be made for nursing and medical attention if the results are not to be disastrous. It is a pity that so much time and energy have been expended in advocating what in the present state of our knowledge can only be characterised as wholly premature. The bibliography, which has neither chronological nor alphabetical order, shows that a very large number of works has been consulted, but all that is of value in the book might well be compressed into one-tenth of the space occupied.

BRITISH HYDROLOGY.

INCREASED attention is being paid to the organisation of British spas, which, although differing in ranges of altitude and temperature from those abroad, do offer in a large number of cases amenities which not only compare favourably with many continental spas in the matter of treatment and comfort, but also save the expense and inconvenience which foreign travel may mean to many patients. During the war, when continental spas were no longer available to British visitors, and when the indicated treatment for many war victims was that provided by baths, the British waters had perforce to be resorted to, with the result that a somewhat neglected branch of medical science and practice in this country received a great impetus. During the past three years a course of lectures on medical hydrology has been given at the London University, arranged by the board to promote the extension of university teaching, and in coöperation with the Committee for the Study of Medical Hydrology in Great Britain. The fee for the course is £1, and in the week during which the course is held, usually at the end of April and the beginning of May, visits are made to, and demonstrations given at, some of the hydropathic centres of the country. Taken in connexion with the work of the British Spa Federation, which includes some of the leading spas complying with a certain standard of efficiency, the lectures are a step towards the organisation of British spas on lines laid down by Dr. Fortescue Fox in THE LANCET last year.[1] These were: (1) the coördination and development of British waters, under medical authority; (2) post-graduate lectures in hydrology at the universities; (3) facilities at one university for the systematic training of hydrologist practitioners. Particulars of the lectures and demonstrations can be obtained from Miss Hilda Fox, care of University Extension Department, University of London, South Kensington, S.W.7.

THE DOCTOR OF THE FUTURE.

UNDER this title Dr. George E. Vincent, the President of the Rockefeller Foundation, discusses the trend of medical practice in the United States. At present the mass of the population, "perhaps 75 to 80 per cent., are treated by general practitioners who have limited technical appliances, little or no specialisation of skill, and slight relation to medical services organised in hospitals, dispensaries, and clinics." Among the forces now at work which will modify the present state of things is the growth of preventive medicine which, by reducing sickness, will limit the material for curative practice. The high cost of sickness is leading to a demand for insurance. The character of a modern medical education is depleting the rural areas of their physicians. Already four types of doctors have emerged from the modern crucible according to Dr. Vincent, who classifies them as follows: "(1) the professorial doctor who teaches and investigates; (2) the specialist; (3) the socialised or full-time salaried doctor; and (4) the individual, independent, general practitioner." Can the latter type, still the most important numerically, continue to survive? he asks, with his increasingly difficult handicaps. While his disappearance would be a serious loss, Dr. Vincent evidently does not look on it as an impossibility. As conditions of survival he postulates coöperation in the use of laboratories and other resources, willingness to take part in insurance schemes, and above all readiness to become a practitioner of preventive medicine.

THE DIPLOMA IN TROPICAL MEDICINE.

IN the Students' Number of THE LANCET under this heading it is stated that systematic instruction for these diplomas is given at the London School of Tropical Medicine, at 5, Endsleigh-gardens, London, N.W. The old London School of Tropical Medicine now forms the Tropical Division of the London School of Hygiene and Tropical Medicine, and the address is 23, Endsleigh-gardens, Euston-road, N.W. 1, and not 5. An account of the activities of the new body was given in THE LANCET of June 27th, 1925 (p. 1354).

Sir StClair Thomson has been appointed hon. consulting laryngologist to the Italian Hospital, London.

Dr. T. Vincent Dickinson has been elected Master of the Society of Apothecaries, one of the oldest of the City Livery Guilds.

EXTENSION OF KIDDERMINSTER HOSPITAL.—In commemoration of his silver wedding the Prime Minister has given £5000 towards the £25,000 required for alterations and additions to Kidderminster District General Hospital, and Mrs. Baldwin recently laid the foundation-stone of the extensions. The scheme embraces an out-patients' department with consulting room, a dispensary, an operating room, a new ward for 40 children, and a laundry.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

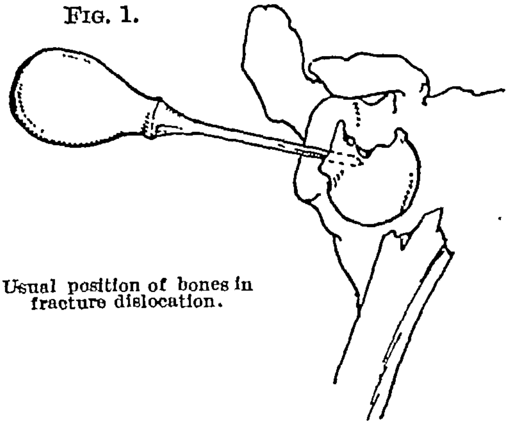
CXXXVII.—FRACTURE DISLOCATIONS OF THE UPPER END OF THE HUMERUS.

THIS complicated injury is fortunately a rare one. It is caused by direct violence upon the shoulder; the same blow which forces the head of the humerus out of the glenoid cavity breaks the neck of the bone. From this it follows that the fracture is often comminuted and that the head is usually rotated so that its axis in no way corresponds with that of the shaft. In this, as in the majority of juxta-articular fractures, a good result can only be obtained by early and exact diagnosis. The severity of the injury will cause so much pain, swelling, and distortion of the shoulder that there ought to be no excuse for neglecting thorough examination.

Dangers of Diagnostic Error.

There are two very real dangers of serious error. One is that of simply putting up the arm with sling and bandage without making an exact diagnosis. In the first place this is done by way of "first-aid" and then, the patient being fairly comfortable, a policy of procrastination is followed for days and then weeks, and when the true nature of the disaster is brought to light by the fixed and painful shoulder on which the X rays are turned for the first time, the chance of cure has passed by and a judge and jury are invited to the consultation.

FIG. 1.



Usual position of bones in fracture dislocation.

The other likely mistake is to recognise the dislocation, by the emptiness of the glenoid cavity and the sagging inwards of the deltoid beneath the acromion, but to overlook the fracture. If then an attempt to treat the dislocation is made, a spurious reduction may be effected by forcing the shaft of the bone into the shoulder-joint and there leaving it. This mistake should be avoided by noticing that the head of the bone does not rotate with the shaft, and that crepitus is often elicited. Of course, the use of the X rays within the first 24 or 48 hours of the accident should be regarded as absolutely essential, and the fact that this rule is so often neglected, with disastrous results, affords a most puzzling comment on the mentality of doctors, who thus carelessly endanger the patient, themselves, and the reputation of the profession.

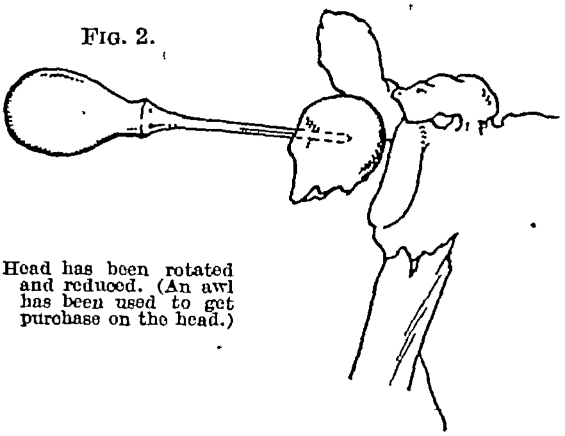
The X ray picture ought to afford a clear indication as to the nature of the injury. The glenoid cavity is empty, the neck of the bone is broken, and the upper fragment is distorted so that its fractured surface is turned away from that of the shaft. (Fig. 1.)

Open Operation and Reduction.

When these facts have been made clear, immediate arrangements should be made for open operation and reduction in a suitable institution. There is no alternative to operative treatment which can afford any hope of a good functional arm, and there is nothing gained by delay or the adoption of any temporising measures.

It is impossible to reduce the dislocation by any manipulation of the arm, because the continuity of the head and shaft of the humerus is broken.

FIG. 2.

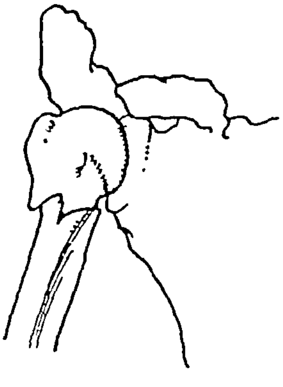


Head has been rotated and reduced. (An awl has been used to get purchase on the head.)

It is useless to wait for consolidation of the fracture and then to hope for reduction of the dislocation, because the alignment of the fragments is so faulty that only gross malunion can occur, and when it has occurred the torn capsule will be so united by scar-tissue as to make reduction impossible.

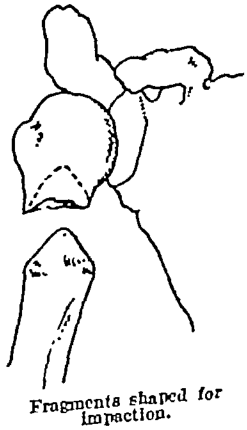
The operation for this injury involves the consideration of three main points—viz., adequate exposure, reduction of the head, and fixation of the fracture. Exposure should be by the ordinary anterior incision along the anterior border of the deltoid muscle. The cephalic vein is exposed and ligatured. Having made a three-inch incision and investigated the underlying conditions, it will probably be of advantage to prolong the incision upwards along the deltoid border to the clavicle, and then to cut outwards towards the acromion. The clavicular origin of the deltoid is cut and the muscle turned outwards. The capsule of the joint may be so much torn that no further division is necessary in order to get at the head of the bone. Otherwise the capsule should be divided by a vertical incision along the line of the long head of the biceps. The humeral head now being exposed, the difficulty consists in putting it back into the glenoid cavity and in rotating it into correct alignment. Probably the tendon of the subscapularis will already be torn, but it ought not to be necessary to cut any of the short rotators unless the operation is being done several weeks after the accident. Manipulations of the head of the bone may be effected by means of a shoe-horn elevator

FIG. 3.



Fracture treated by simple impaction.

FIG. 4.

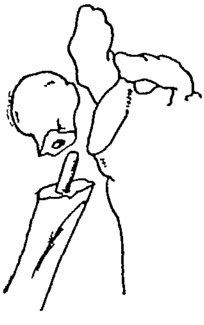


Fragments shaped for impaction.

or by transfixing it with a stout bone-drill on a handle. (Fig. 2.)

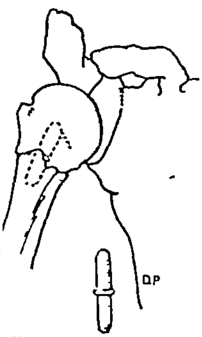
When the head has been restored to its socket with its broken surface directed towards the axis of the arm, fixation of the fracture can be effected. In most cases this fixation does not require any special apparatus. The fracture is recent and the ends of the bone are jagged. All that is necessary is by traction and leverage to fit the ends together (Fig. 3), when the tension of the muscles may be trusted to keep them in apposition. If the bone ends are oblique or have become so smooth that they will not lock, then some impaction may be necessary. Often the shaft will present an outstanding point which may be trimmed up and forced into a cavity gouged out of the head. (Fig. 4.) Or else an intra-medullary peg, two inches long and a quarter of an inch thick, with a central stop may be used. This is first hammered tightly into the shaft and the projecting end is manœuvred into a hole drilled in the axis of the head. (Figs. 5 and 6.) Whatever method of fixation is used, great care should be taken to secure correct orientation of the fragments in regard to rotation. The operation is concluded by suturing of the capsule, the clavicular origin of the deltoid and the skin. The arm is put up in moderate abduction for the first few days with an axillary pad and a sling. Then, when the patient can sit up the arm is put on to an abduction splint, which is retained for four to six weeks. After the first ten days the splint is removed daily for exercise and massage.

FIG. 5.



Union by pegging. Peg inserted into distal fragment.

FIG. 6.



United over a peg. Inset shows the peg with central stop.

If the patient's condition contra-indicates a general anæsthetic, the operation may be performed under local anæsthesia, by infiltrating the brachial plexus with 2 per cent. solution of novocaine. If the patient refuses an open operation, then the arm should be put up in full abduction from the outset.

Late Operation.

If the nature of the case has been overlooked, and treatment has to be undertaken six weeks or more after the accident, then an attempt may be made to carry out the reconstructive operation above described, but it will seldom be found possible because the head of the bone has become so fixed and also so atrophied. Under these circumstances the head must be removed, whilst the shaft, which may be rounded off, is placed in the glenoid cavity. But at the best this operation will only secure a weak joint for which a subsequent arthrodesis may have to be done.

ERNEST W. HEY GROVES, M.D., B.Sc.,
M.S. Lond., F.R.C.S. Eng.,
Surgeon to the Bristol General Hospital;
Professor of Surgery, University of Bristol.

STUDENTS' GUIDE—SESSION 1925–26.

DENTAL SURGERY.

APPEARANCE on the Medical Register entitles a practitioner to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but few dental appointments at general or special hospitals or dispensaries are available save to those with a special diploma.

In THE LANCET of August 29th we outlined the constitution of the Dental Board of the United Kingdom, and the regulations in regard to the registration of dental students.

The Examining Bodies in Dentistry which grant degrees or diplomas in the subject are as follows:—

Royal College of Surgeons of England.—Licence in Dental Surgery.

Royal College of Surgeons, Edinburgh.—Licence in Dental Surgery. The College also grants a Higher Dental Diploma which is registrable in the Dentists Register as an additional qualification.

Royal Faculty of Physicians and Surgeons of Glasgow.—Licence in Dental Surgery. The curriculum, which is similar to that of Edinburgh, includes in addition dental bacteriology.

Royal College of Surgeons in Ireland.—Licence in Dental Surgery.

University of Birmingham.—Dental licence; degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

University of Bristol.—Licence in Dental Surgery; degrees of Bachelor and Master of Dental Surgery (B.D.S. and M D.S.).

University of Durham.—Licence in Dental Surgery; degrees of Bachelor of Dental Surgery (B.D.S.) and of Master of Dental Surgery (M.D.S.).

University of Leeds.—Licence in Dental Surgery; degrees of Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.).

University of Liverpool.—Licence in Dental Surgery; (L.D.S.); degrees in Dental Surgery (B.D.S. and M.D.S.).

University of London.—Degree of Bachelor in Dental Surgery.

University of Manchester.—Degrees of B.D.S.; and a licence in Dentistry.

University of Sheffield.—Degree of Bachelor of Dental Surgery; and the diploma of Licentiate in Dental Surgery.

Queen's University of Belfast.—Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery.

In the following syllabus the respective requirements of the various examining bodies in dentistry are set forth, together with the facilities for dental study offered by certain other institutions.

THE EXAMINING BODIES IN DENTISTRY.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have passed the required Preliminary Examination in General Education before Jan. 1st, 1923.

Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. 1. Preliminary Science Examination.—This is identical with Part I. of the First Examination of the Examining Board in England. Candidates must pass the Preliminary Science Examination before commencing the courses required for the Second Professional Examination. 2. The First Professional Examination.—The candidate must produce evidence of instruction in Dental Metallurgy and Practical Dental Mechanics. The Examination consists of Part I. (Mechanical Dentistry), Part II. (Dental Metallurgy and the Properties of Dental Materials), the examination in Dental Metallurgy being by written paper, and Part III. (a) General

Anatomy and Physiology, (b) Dental Anatomy and Physiology conducted by papers and vivâ voce examination. The parts may be taken together or separately. 3. The Second Professional Examination.—This is divided into two parts: (a) the General, (b) the Dental. The General part must be passed before the Dental portion. The instruction is obtained partly at a General Hospital and partly at a Dental Hospital. The Second Professional Examination consists of: Part I., General Surgery and Pathology; Part II., Dental Surgery and Pathology, and Practical Dental Surgery. There is a written and vivâ voce examination in each part and a practical examination as well in Part II. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination for any degree or qualification in Medicine or Surgery registrable under the Medical Act of 1886. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Universities above mentioned. The fee for the diploma is 20 guineas, and is payable as follows: Preliminary Science Examination, for each admission to Part I., £3 3s.; Part II., £2 2s. First Professional Examination, for each admission to Part I., £4 4s.; Part II., £1 1s.; Part III. (a) £2 2s.; (b) £2 2s.; Second Professional Examination, for each admission to Part I., £2 2s.; Part II., £4 4s.

The following Regulations apply to all candidates who pass the Preliminary Examination in General Education on or after Jan. 1st, 1923.

1. Candidates for the Licence in Dental Surgery of the Royal College of Surgeons of England are required to pass one of the Examinations in General Education recognised by the Conjoint Examining Board in England, and the Pre-Medical Examination in Chemistry and Physics conducted by that Board or one of the examinations recognised in lieu thereof, before they commence the curriculum of professional study for the Licence extending over four years.

2. Candidates who produce evidence of having been registered by the General Medical Council as Medical or Dental Students on or after Jan. 1st, 1923, will be considered to have passed the required Preliminary Examination in General Education and the Pre-Medical Examination.

3. Candidates who hold the degree of D.M.D. Harvard, D.D.S. Pennsylvania, D.D.S. Michigan, D.D.S. Illinois, D.D.S. St. Louis, Missouri, D.D.S. Northwestern University, Chicago, D.D.S. Minnesota, D.D.S. Tufts College, Boston, B.D.S. Sydney, or the Licence of the Dental Board of Victoria, Australia, are not required to pass these Examinations.

First Professional Examination.—1. The First Professional Examination consists of Part I. Dental Mechanics, Part II. Dental Metallurgy and the Properties of Dental Materials and Part III. Section (a) General Anatomy and Physiology, Section (b) Dental Anatomy and Physiology, and is held in January or February, April, and September or October in each year.

2. Candidates may present themselves for the several Parts of the First Professional Examination together or separately, but before admission to any part of the Examination they must produce evidence of having passed the required Preliminary Examination in General Education and the required Pre-Medical Examination or a certificate of having been registered as a Medical or Dental Student by the General Medical Council.

Part I. *Dental Mechanics.*—3. This Examination is a practical one, conducted in the Mechanical Laboratory of one of the Dental Hospitals in London.

4. Candidates must give 21 days' notice in writing of their intention to present themselves for the Examination, and at the same time forward certificates:—

(1) Of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Dental Mechanics. One year at least of this study must be taken in the Mechanical Department of a recognised Dental Hospital where the arrangements for teaching Dental Mechanics are satisfactory to the Board of Examiners in Dental Surgery. Part or the whole of the rest of the course may be taken as a pupil with a competent dentist provided that time spent as a private pupil shall be at least twice the time required for the corresponding instruction* taken at a Dental School.

(2) Of having attended at a recognised Dental Hospital and School: (a) A course of lectures on Dental Mechanics; (b) a course of Practical Dental Mechanics, including the manufacture and adjustment of 6 dentures and 6 crowns.

6. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of having received three months further instruction under the conditions specified in Certificate (1) paragraph 4.

Part II. *Dental Metallurgy and the Properties of Dental Materials.*—7. This Examination is conducted by written paper.

8. Candidates must give 21 days' notice in writing of their intention to present themselves for the Examination, and at the same time forward a certificate:—Of having attended at a recognised Dental Hospital and School: (a) A course of lectures on Dental Metallurgy; (b) a course of Practical Dental Metallurgy.

9. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of having worked in a Dental School, to the satisfaction of the Dean, for a further period of three months.

Part III. (a) *General Anatomy and Physiology*, (b) *Dental Anatomy and Physiology.*—10. This Examination is partly written and partly oral.

11. Candidates may enter for Section (a) only or for Sections (a) and (b) together on producing the required certificates, but they will not be allowed to proceed with Section (b) until they have passed in Section (a). In the case of a candidate who enters for both Sections and fails in Section (a) the fee paid for admission to Section (b) will not be forfeited, but will be credited to the candidate on readmission to examination in that Section. Candidates who enter for both Sections together may pass in Section (a) although failing to pass in Section (b).

12. Candidates must give 21 days' notice in writing of their intention to present themselves for the whole or for one Section of this examination and at the same time forward certificates:—

(1) For Part III. (a). Of having attended at a recognised Medical School: (a) Courses of instruction in Anatomy, including special demonstrations on prepared dissections during three terms; (b) a course of dissections to include, if possible, the head and neck, during one term; (c) courses of instruction in Physiology, including General Biology, Biochemistry, and Biophysics, during three terms; (d) a course of instruction in Histology.

(2) For Part III. (b). Of having attended at a recognised Dental School: (a) A course of instruction in Dental Anatomy and Physiology; (b) a separate course of instruction in Dental Histology, including the preparation of Microscopical Sections.

13. A candidate referred at this examination who does not hold a registrable Dental Qualification will be required, before readmission to Section (a), to produce a certificate of three months' additional study of Anatomy and Physiology at a recognised Medical School, and will be required before readmission to Section (b) to produce a certificate of having worked

---

* This instruction may be taken prior to the date of passing the Examination in General Education and the Pre-Medical Examination, but will not be counted as part of the required four years of professional study unless taken after passing the Pre-Medical Examination.

in a Dental School, to the satisfaction of the Dean, for a further period of three months.

14. *Exemptions.*—Candidates who have passed Section I. of the First Professional Examination of the Conjoint Examining Board in England, or who produce evidence of having passed the Examination in Anatomy and Physiology for a degree, or other qualification, in Medicine or Surgery, registrable under the Medical Act of 1886, or for the degree of M.B. or M.D. of a Foreign or Colonial University recognised by the Conjoint Examining Board in England, are not required to pass Section (*a*).

Second Professional Examination.—1. The Second Professional Examination is held in February, May or June, and November in each year, and consists of: Part I., General Surgery and Pathology; Part II., *Dental Surgery and Pathology, and Practical Dental Surgery.*

2. Candidates who have passed the First Professional Examination at least six months† previously may present themselves for Part I. only on producing the certificates mentioned in paragraph 6 of this section, or they may enter for the whole Examination at one time on producing the certificates mentioned in paragraphs 6 and 10 of this section.

3. Candidates must pass in Part I. before proceeding to Part II.

4. Candidates who enter for the whole Examination at one time may pass in Part I. although failing to pass in Part II.; but if they fail to pass in Part I. they will not be allowed to proceed with the Practical and Oral Examinations in Part II. In such cases the fee paid for admission to Part II. will not be forfeited, but will be held over until such time as the candidate is readmitted to examination in that Part.

Part I. *General Surgery and Pathology.*—5. This Examination is partly written and partly oral.

6. Candidates must give 21 days' notice in writing of their intention to present themselves for this Examination, and at the same time forward certificates:—

(1) Of having attended at a recognised Medical School: (*a*) A course of instruction‡ in Surgery during two terms; (*b*) a course of instruction in Medicine during two terms; (*c*) a course of instruction in General Pathology (including Bacteriology) during two terms. (2) Of having *acted as* Surgical Dresser in the Out-patient Department of a recognised Hospital for three months. (3) Of having attended, at a recognised Hospital or Hospitals, the practice of Medicine and Surgery, including clinical lectures, *for* 12 *months.* (4) Of being 21 years of age.

7. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of such additional study during three months at a recognised Medical School and Hospital as the Teachers of the School may determine.

Exemptions.—8. Candidates who are Members of the College or who have passed the Examination in Surgery of the Conjoint Examining Board in England, or who produce evidence of having passed the Examination in Surgery for a Degree, or other Qualification in Medicine or Surgery registrable under the Medical Act of 1886, are not required to pass Part I. of the Second Professional Examination.

Part II. *Dental Surgery and Pathology.*—9. This Examination is partly written, partly oral, and partly practical. The oral examination is conducted by the use of preparations, casts, drawings, &c. At the practical examination candidates may be examined:—

(*a*) On the treatment of Dental Caries, on the preparation and treatment of teeth by filling with gold or other material, by inlaying or by crowning, and on other operations *in Dental Surgery.* (Candidates must provide their own instruments.) (*b*) On the treatment of abnormalities of position of the teeth of children. (*c*) On Clinical cases.

10. Candidates must give 21 days' notice in writing of their intention to present themselves for this Examination, and at the same time forward certificates:—

(1) Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a Medical or Dental Student, or of having passed the Pre-Medical Examination conducted or recognised by the Conjoint Examining Board in England. (2) Of having attended at a recognised Dental Hospital and School: (*a*) *A course of Dental Surgery and Pathology*; (*b*) a separate course of Practical Dental Surgery; (*c*) a course of Dental Bacteriology; (*d*) a course of Dental Materia Medica; (*e*) a course of practical instruction in the administration of such Anæsthetics as are in common use in Dental Surgery. (3) Of having attended at a recognised Dental Hospital and School, or in the Dental Department of a recognised General Hospital, the practice of Dental Surgery during two years.

11. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required before admission to re-examination to produce a certificate of three months' additional study at a recognised Dental Hospital.

Fees.—The fee for the Diploma in Dental Surgery is 20 guineas.

Synopses of examinations and all further information can be obtained from the Director of Examinations, Examination Hall, Queen-square, London, W.C. 1.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—Regulations giving a list of Preliminary Examinations recognised for obtaining the Licence in Dental Surgery, as well as of the subjects of the Professional Examinations, may be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, at 49, Lauriston-place, Edinburgh. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates must also have attended a course of instruction at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the Diploma in Surgery. In addition they will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, special courses of lectures and instruction in Anatomy and Physiology (Human and Comparative), Surgery, Pathology, Materia Medica, Dental Histology, and Practical Dental Mechanics and Metallurgy; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Practical instruction in Mechanical Dentistry from a registered Dentist, or in the Mechanical Department of a recognised Dental Hospital and School, for three years. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination, and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the required courses. The examination embraces (1) Chemistry and Physics; and (2) *Anatomy and* Physiology. The fee is £5 5*s.* for the complete examination, and £3 3*s.* is payable for each division. In all cases of rejected candidates the fee for re-entry is £3 3*s.* Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £10 10*s.*, for re-entry £5 5s. The examination embraces (1) Surgery and Medicine; and (2) the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Materia Medica, Dental Mechanics and Dental Metallurgy, with a practical as well as the written and oral examinations in the subjects of Dental and Oral Surgery, Pathology, and Mechanics. The candidate will be tested in the Treatment of Dental Diseases, in Operative Dentistry, the Administration of Anæsthetics, Orthodontics, and in Prosthetic and Mechanical Dentistry. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations or other recognised examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £15 15s. payable for the dental diploma. Candidates applying for copies of Regulations should state date of registration as a dental student. Fees and schedules must be lodged with the Clerk not later than one week before the examination.

---

† The interval of six months is not required in the case of a colonial or foreign dentist.

‡ These courses of instruction must be attended after the completion of the courses in Anatomy and Physiology.

Separate Regulations are issued for candidates registered as Dental Students after Jan. 1st, 1923, for whom there is a much more extended course.

Higher Dental Diploma.—The College grants a Higher Dental Diploma which is registrable in the Dentists Register as an additional qualification. Every candidate for the Higher Dental Diploma shall produce evidence that he has been engaged in the study or practice of his profession as a Registered Dentist for at least one year subsequent to his having obtained the Licence in Dental Surgery of the College, or a Licence or Qualification in Dental Surgery specially recognised by the College. Particulars as to the examinations can be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, 49, Lauriston-place, Edinburgh. The fee payable by Licentiates of the College is £15 15s. For all other candidates £21. A fee of £10 10s. is retained for examination expenses in the case of referred candidates.

The examination embraces the following branches of Dental Science and practice: Dental Surgery, Anatomy, Pathology and Bacteriology, Prosthesis, Anæsthesia, and Dental Radiology. The examination will be clinical and practical as well as written and oral. Candidates will be expected to show a high degree of knowledge and skill.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh, but embrace Dental Bacteriology. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics, and the third Anatomy and Physiology. The examination in Dental Mechanics is practical; and there is at the Final Examination an examination in Practical Dentistry conducted in a dental hospital. Copies of regulations, &c., to be obtained from Mr. Walter Hurst, Registrar, Faculty Hall, 242, St. Vincent-street, Glasgow. Candidates applying for Regulations should state date of registration as a dental student.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Candidates for the licence in Dental Surgery are required to pass three professional examinations, and to produce certificates of having, subsequently to registration as a Dental Student, passed the examination in Biology, and attended courses of instruction in the following subjects at a recognised school of medicine: (*a*) Human anatomy, with dissections and demonstrations, for three academic terms. (*b*) Physiology, theoretical and practical, including Dental Physiology lectures for two academic terms. (*c*) Histology, for one academic term. (*d*) Chemistry and Physics as applied to Dentistry. For the second examination certificates must be produced of having attended, at an institution recognised by the College for the purpose, the following courses: (*a*) General Pathology (including Bacteriology) for three academic terms. (*b*) Medicine for two academic terms. (*c*) Surgery for two academic terms. (*d*) The practice of a general hospital, with certified instruction in Clinical Medicine, Clinical Surgery, and Venereal Diseases, for three academic terms. For the final examination evidence must be produced of having been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the direction of the Superintendent of the Mechanical Department of a recognised Dental Hospital where the arrangements for teaching Mechanical Dentistry are satisfactory to the Council of the College; of having attended, at a recognised institution, courses of instruction in (*a*) Dental Surgery and Pathology, Orthodontia, and the Materia Medica and Therapeutics applicable to Dental Surgery. Lectures. Two courses. (*b*) Dental Mechanics. Lectures. Two courses. (*c*) Anæsthetics. One course. (*d*) The practice of a Dental Hospital, or of the Dental Department of a General Hospital. Twenty-four calendar months. (*e*) Dental Metallurgy. (*f*) A course of Radiology; of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a Dental Student; four years of professional study; and of being 21 years of age.

The subjects of the first examination are Anatomy, General, and Physiology and Histology. For the second examination (*a*) General Pathology (including Bacteriology), (*b*) Medicine and Surgery. For the Final Examination, General Surgery and Dental Pathology, with the Materia Medica and Therapeutics applicable to Dental Surgery, Dental Mechanics and Metallurgy, Anæsthetics, Orthodontia. Candidates must pass in all the subjects set at each examination which in the second and final parts will be partly vivâ voce and partly practical, and will include the examination of patients and the performance of dental operations. The total fee for the Diploma in Dental Surgery is 21 guineas.

UNIVERSITY OF BIRMINGHAM.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board. The instruction at the Dental Hospital is carried out under the direction of the University Dental Clinical Board, so that students may fully qualify themselves for the Dental Diploma (L.D.S.) of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum: The "John Humphreys Odontological Museum." An Entrance Exhibition, value £37 10s., is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—

1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A.* In addition to the Licence in Dental Surgery the candidate must produce *evidence that he has attended* the courses required by medical students of the University in the following subjects and passed the Examinations held in the same *for Medical and Surgical* Degrees: (*a*) Elementary Biology and Organic Chemistry, (*b*) Anatomy and Practical Anatomy, and (*c*) *Physiology and Practical Physiology. B. That he has passed the class examinations in*: (*d*) One Special Course of Lectures on Medicine, (*e*) One Special *Course of Lectures on* Surgery, and (*f*) *Pathology* and Bacteriology. *C.* That he has attended courses and passed the class examinations in: (*g*) Dental Histology and Patho-Histology, (*h*) Comparative Dental

Anatomy, and (*k*) Dental Surgery and Prosthetic Dentistry. *D.* That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D.* 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work, and investigations in some subject connected with Dentistry, which theses shall be submitted to examiners to be nominated by the Dental Advisory Board.

UNIVERSITY OF BRISTOL.—Candidates for the degree of Bachelor of Dental Surgery must be not less than 21 years of age and shall have pursued the courses prescribed by University regulations during not less than four years after passing the first examination in the subjects of Chemistry and Physics, of which three shall have been passed in the University. All candidates for the degree of B.D.S. are required to satisfy the examiners in the several subjects of four examinations. The First Examination: The subjects are Chemistry, Physics, and Biology, and the curriculum extends over one year.* The Third Examination: The subjects are Dental Mechanics, Dental Metallurgy, and Dental Materia Medica, and the candidate shall produce evidence of having served for three years an approved pupilage in Dental Mechanics.† The Second Examination: The subjects are Anatomy, Physiology, and Histology, Dental Anatomy, and Dental Histology. The Final Examination: The subjects are Medicine and Surgery, Dental Surgery (including Prosthetics), Operative Dental Surgery, and Dental Bacteriology. Degree of Master of Dental Surgery: Candidates shall be Bachelors of the University, shall present a Dissertation on some subject of Dental Surgery to be approved by the Examiners, and pass an examination in Dental Surgery. Diploma in Dental Surgery: Candidates need not be undergraduates, but shall have passed an entrance examination satisfactory to the University before being admitted to any professional examination; the curriculum extends over four years from the date of passing a preliminary science examination in Chemistry and Physics. A three years' pupilage in Mechanical Dentistry is required† and four examinations must be passed, the subjects of which agree with those of the B.D.S. Medicine is not required for the Final Examination. Candidates who are already registered medical practitioners shall be further exempted from study and examination in Physics and Chemistry, Anatomy, Physiology and Histology, Medicine, and General Surgery.

UNIVERSITY OF DURHAM.—Every Dental student must, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for Medical students.

Licence in Dental Surgery: The first examination consists of three parts, which may be passed separately. Part 1, Organic Chemistry. Part 2, Biology. Part 3, Theoretical Dental Mechanics, Dental Metallurgy (Theoretical and Practical). Second Examination: Anatomy, Physiology (including Biochemistry and Biophysics), Dental Anatomy and Dental Histology. Third Examination: Pathology and Bacteriology, Practical Dental Mechanics, Dental Materia Medica and Therapeutics. Final Examination: Medicine, Surgery, Dental Surgery and Pathology, Orthodontics, Operative Dental Surgery, and Dental Prosthetics, and Anæsthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the required subjects, attended after registration as a dental student at recognised Colleges or Schools.

Degree of Bachelor of Dental Surgery (B.D.S.).—(*a*) For students taking their complete course of instruction in the University. Such students must pass the same matriculation tests as medical students, and the same pre-registration examination in Inorganic Chemistry and Physics. After registration students must spend five years in the University, on attendance on such subjects as Senate, on the recommendation of the Board of the Faculty of Medicine, may from time to time determine. They must attend the practice of the Newcastle-upon-Tyne Dental Hospital for not less than two and a half years. Six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations.

The subjects of the *first* examination are Biology, Organic Chemistry, and Dental Mechanics and Metallurgy.

The subjects of the *second* examination are Anatomy, Physiology, Dental Anatomy and Histology.

The subjects of the *third* examination are Pathology and Bacteriology, Dental Materia Medica and Therapeutics, and Practical Dental Mechanics.

The subjects of the *final* examination are Medicine, Surgery, Dental Surgery and Pathology, and Orthodontia and Operative Dental Surgery. In this subject knowledge of a much higher standard, and more advanced practical work, is required than for the Licence in Dental Surgery.

(*b*) For candidates possessing a Licence in Dental Surgery of a British University. Candidates must study for at least one year in the University. During such year they must (*a*) attend a course of instruction in Pathology and Bacteriology, and (*b*) spend at least six months in the Newcastle-upon-Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examinations for the degree of Bachelor of Dental Surgery.

Degree of Master of Dental Surgery (M.D.S.)—Every candidate for this degree must be a Bachelor of Dental Surgery of the University of not less than two years' standing, and present an essay embodying original work and research in some subject connected with dentistry. They must also perform to the satisfaction of the examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations, and the fees payable by candidates are as follow:—For the Licence in Dental Surgery: First, Second, and Third Examinations, each £3 10*s.*; Final Examination, £5; for Licence, £3; total, £18 10*s.* For the Bachelor of Dental Surgery: First, Second, and Third Examinations, each £5; Final Examination, £8; for the degree, £6 10*s.*; total, £29 10*s.* For the Master in Dental Surgery: examination, £5; degree fee, £6 6*s.* The practical examinations in dentistry are conducted at the Newcastle Dental Hospital.

UNIVERSITY OF LEEDS.—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery shall be required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the First Examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will be admitted to the degree who has not attained the age of 21 years on the day of graduation. The Diploma in Dental Surgery (L.D.S.) is awarded to successful candidates after attendance on approved courses extending over not less than four years. The curriculum for the Diploma now includes the study of Biology for the First Examination. The classes in the Department of Dentistry begin on Oct. 1st. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology are given in the main buildings of the University. The classes in the other subjects and the systematic courses in Dental subjects are held in the School of Medicine of the University in Thoresby-place. The clinical instruction is given in the Dental Hospital at the Leeds General Infirmary. Applications for the prospectus should be made to the Academic Sub-Dean of the Faculty of Medicine.

---

* Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination for either the B.D.S. or the L.D.S., and will be regarded as having completed one year of study.

† This pupilage must be taken either in the University laboratories or those of some institution recognised for the purpose by the University.

UNIVERSITY OF LIVERPOOL.—The University grants a Licence in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The management of the curriculum (lectures, practical and clinical) is in the hands of the University Board of Dental Studies. The courses of systematic instruction are given in the main University buildings, and those in Dental Mechanics, Operative Dental Surgery, &c., are given in the University School Extension (opened 1922), adjoining the Dental Hospital, the laboratory of which is in charge of a skilled dental mechanic under the supervision of the Director of Dental Education. The clinical instruction is given in the Dental Hospital. Students can take the whole curriculum, including Dental Mechanics, at the University School of Dental Surgery. The times of the lectures at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. Fees: The fees for the complete courses, including Pupilage and Hospital Practice, are as follows: Degree of B.D.S., £250; M.D.S. (by research, £32; by examination, £27); L.D.S. (Liverpool), £198. Further information may be had from the Director of Dental Education, Prof. W. H. Gilmour.

In order to be admitted to the Bachelor's Degree in Dental Surgery a student must normally, after registration as an Internal Student, have—(1) Attended prescribed courses of study for five years at one or more Schools of the University. (2) Passed the following examinations:—(*a*) First Examination: *Part A:* (i.) Chemistry, (ii.) Physics, (iii.) Biology (Zoology and Botany); *Part B:* (iv.) Dental Metallurgy. Candidates may take Parts A and B separately. (*b*) Second Examination: *Part A* (i.) Anatomy, (ii.) Dental Anatomy, Dental Physiology, and Dental Histology; *Part B:* (iii.) Physiology; *Part C:* (iv.) Dental Mechanics. Candidates may take Part A separately but must take Parts B and C together. Third Examination: *Part A:* (i.) Elementary Bacteriology, (ii.) Clinical Chemistry, (iii.) General Pathology; *Part B:* (iv.) Dental Materia Medica, (v.) Dental Mechanics and Dental Prosthetics. Candidates may take Parts A and B separately. Students who have received not less than two years' instruction in Dental Mechanics previous to Nov. 30th, 1922, with a Dentist registered under the provisions of the Dentists Act (1921) and who have passed a recognised examination in preliminary education may, on application, be registered as students for the Licence under certain conditions.

UNIVERSITY OF LONDON.—The curriculum for the degree of Bachelor of Dental Surgery covers five years from Matriculation. The Regulations for Internal and External Students may be obtained post-free on application to the Principal Officer, at the University.

UNIVERSITY OF MANCHESTER.—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any other school in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the requirements of students preparing for the B.D.S. Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given throughout the session both at the University and at the Dental Hospital of Manchester adjoining the University. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department, and for them common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 94½ guineas, payable in three equal yearly instalments. The composition fee for candidates for the University Diploma in Dentistry is 84½ guineas, payable in three equal yearly instalments. The composition fee for candidates for the L.D.S. of England is 94½ guineas, payable in three equal yearly instalments. Students who have already served their apprenticeship with a private practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The composition fee does not include the hospital fees, the examination fees, nor the fee for the conferment of the degree or the diploma.

UNIVERSITY OF SHEFFIELD.—*Degree of Bachelor of Dental Surgery.*—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five and a half years subsequent to matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year after matriculation and the passing of the further examination in Chemistry and Physics. Second Examination: The subjects of the examination are Anatomy, Physiology, Dental Anatomy, Physiology and Histology; Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are: Part I., Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed five and a half years of professional study.

Degree of Master of Dental Surgery.—Candidates must have passed the examination for the degree of B.D.S. at least one year previously and before admission to the examination must have held for not less than six months a dental appointment in a hospital affording full opportunity for the study of Dental Surgery. Candidates shall not be required to but may present a thesis embodying observations in some subject approved by the Faculty and a candidate whose thesis is of exceptional merit may be exempted from any part of the examination.

Diploma of Licentiate in Dental Surgery.—A candidate must have attained the age of 21 years on the day upon which he is to receive the diploma, and have pursued the courses of study required by the University regulations during a period of not less than four years subsequently to passing the preliminary examination and the passing of the further examination in Chemistry and Physics. Two years must be passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year. Second Examination: The subjects of the examination are Anatomy and Physiology, Dental Anatomy and Physiology, Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are: Part I., Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed the fourth year of professional study.

The Dental Composition Fee is £25 for each year of the course. In addition a fee of £50 is payable each year the student receives instruction in Mechanical Dentistry in the Dental Department.

QUEEN'S UNIVERSITY OF BELFAST.—The following degrees and diplomas are now conferred: Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery. Lecturers have been appointed in Dental Surgery, Dental Mechanics, Dental Metallurgy and Materia Medica, and Orthodontia.

The TEACHING INSTITUTIONS will be summarised in the sequel.

(To be continued.)

Special Articles.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 403.)

EVIDENCE OF NURSING AND OTHER WOMEN'S ORGANISATIONS.

Queen Victoria's Jubilee Institute for Nurses.

(App. LXXII. and Q. 10400–19582.)

THIS evidence was submitted by Miss Peterkin, Mrs. Bruce Richmond, and Major H. F. Cadell. The Institute was incorporated by Royal Charter in 1889 with the object of training and providing nurses for work among the sick poor in their own homes. The principal functions of the Institute are the organisation of local nursing associations, the selection, training, and supply of nurses, and the supervision of their work while in the service of the local associations. The conditions for affiliation of nursing associations are mainly (1) that the work should be carried out under the direction of the medical practitioners; (2) that it should be inspected periodically from the Institute by a nursing expert; (3) that it should be unsectarian; (4) that the nurses' services should be primarily for those unable to employ a private nurse, and that the necessitous poor should be nursed free.

The cost of domiciliary visits varies somewhat widely, but the average rate of payment works out at 1*s*. 4*d*. Arrangements which have been made with many approved societies have been of two kinds—

Those in the first group make payment at the rate of 1*s*. 4*d*. a visit for the first 30 visits and then at the rate of not more than 5*s*. a week; those in the second at the rate of 1*s*. a visit, the Nursing Association collecting from the patient, if it wishes to do so, the additional 4*d*. a visit which makes up the average cost. Payment for the nursing of chronic cases is not made by those in the second group; both make a payment of 5*s*. for a nurse's attendance at an operation.

The contention of the Council of this Institute was that there is in existence an organised national service capable of covering the whole country and it urged that nursing should be provided for all insured persons. It was thought that such a service could be provided at a capitation fee of 1*s*. per insured person.

Asked whether, if such a service were made available, there would be much point in having a nursing association and a local authority supervising it, the witnesses deprecated the employment of nurses by the local authority and urged that the work should be done through the existing associations; they desired to make no suggestions as to who should administer it on the insurance side. The reason why, up to the present, nursing had not been greatly in favour as an additional benefit was partly due to the system of payment by visit and partly due to the too-sure feeling that nursing arrangements were already freely available to insured and uninsured alike. The witnesses did not think that imposing a charge on National Health Insurance funds would injure the flow of voluntary subscriptions, but such a charge would entitle insured persons to priority of service.

In the Scottish part of this evidence it was stated that 80 per cent. of the homes of the people are quite suitable for the nursing care of all illnesses excepting only those requiring major surgical operations, and that while there are some rural areas still unnursed, the greatest need is for an expansion of the existing service in industrial centres, which it would not be difficult to arrange.

College of Nursing.

(App. LXXIII. and Q. 19583–10265.)

The College of Nursing has a membership of over 23,000 trained nurses, and is the largest organisation of trained nurses in the Kingdom. Miss J. P. Watt, Miss G. Bremner, and Miss H. Viney gave evidence. The Council of the College recommend: (1) The provision of a statutory nursing benefit complemental to medical benefit from National Health Insurance funds; (2) that the staff employed for visiting care be fully qualified general-trained nurses with additional district training; and (3) that the visiting nursing care of the insured should be coördinated with other public nursing services, and that where resident care is required, the services of private nurses be utilised. They pointed out that the importance of trained domiciliary nursing has been much stimulated by the statement in 1914 of the then Prime Minister that any system of doctoring was hopelessly inefficient which was not supplemented by a good system of nursing. Notwithstanding this, nursing was still left very largely to voluntary enterprise. It was suggested that the Council's proposed scheme should be financed by a capitation payment of 1*s*. per insured person, with supplemental grants towards the cost of training and (experimentally) for the maintenance of a limited residential nursing service.

On the question of free choice of nurse the witnesses said that there was no analogy between the profession of nurse and panel doctor. Free choice of nurse is not feasible for economic reasons; also it was pointed out that a person going into a nursing home or a hospital cannot have choice of nurse. The witnesses thought that, amongst other things, a nursing service would bring home to the people the general benefit under the Act, because they would get a larger amount of individual attention.

(Q. 10506.) For example, you get a case of an abscess; it does not take the doctor very long to open it if you have a local anæsthetic; but it does take a nurse many days with dressings to get it healed. The same applies to pneumonia, where a doctor's visits would be about a quarter of an hour, whereas the nurse would spend nearly two hours, coming twice a day and perhaps a third time.

The witnesses estimated that 8 per cent. was the minimum number of insured persons requiring nursing and that this would increase as the value of the service became known.

(Q. 10505.) Would you agree that a nurse should be provided to attend upon an insured person only on the recommendation of the doctor in charge of the case?—It is an established practice now in district nursing that the people are at liberty to requisition the service, and after paying the first visit (unless it be a very trivial matter) the nurse arranges for or tells the people to call the doctor, and thereafter the doctor and nurse continue the treatment together.

It was thought that there was an adequate supply of trained nurses to meet the present needs of the insured population, and that the service would rapidly expand with improved conditions.

(Q. 10508.) The College wants an inclusive minimum salary of £250 a year, with allowances, as a living wage for these women; that would make the service attractive to them. The extra factors we have to consider in the district service work are the wear and tear of clothes, and the struggling against all weathers.

---

* References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1169.

A nursing service should be a good business proposition and should progressively reduce sickness benefit claims. Its business value has been recognised by the Metropolitan Life Assurance Company of New York, who, last year, spent $500,000 on nursing.

Incorporated Midwives' Institute; Scottish Midwives' Association.

(App. LXXIV. and LXXV. and Q. 19626–19703.)

Evidence was given by Miss Doubleday, Miss M. Gilligan, and Miss J. C. Barker. These witnesses indicated certain delays and other points of criticism of the administration of maternity benefit and the way in which these objections should be met. They urged that in addition to the cash payment, maternity benefit should include antenatal treatment. They also recommended that sick pay should be given for four weeks after the confinement both to the woman who is the wife of an insured person, and to the woman who is herself an insured person.

The Scottish evidence included a complaint that many general practitioners who had given up their poorer class midwifery practice were now resuming it, but employing untrained women. The Midwives' Association protest that this imperils the livelihood of their members and was a positive danger to infant life. While recognising that it was a serious offence to "cover" an unqualified woman, they said that none the less this was done.

(Q. 19664.) You would make the benefit available only if the labour has been conducted by a medical practitioner or a certified midwife?—Unless in a genuine emergency. We always allow for that.

With regard to the question whether the cash payment of maternity benefit was abused, the witnesses said that the mother was the right person to have it, although, in fact, it was sometimes misapplied.

(Q. 19652.) I do not say that the money is abused exactly. The position is this, that if they are living on the dole, as a very large number in Glasgow are just now, they are inclined to get a little bit behind with their rent, and they will say: "We will make that right when we get our maternity benefit," and it goes to the rent, or some necessary purpose, instead of to the midwife.

As regards antenatal treatment, the witnesses were asked whether this was not already given as part of medical benefit by the doctor, and they replied that a midwife undertakes her own antenatal work and advises medical supervision when it is necessary. In the case of a woman who is the wife of an insured man she is not entitled to receive medical benefit by the doctor.

The insistence of the witnesses on the fact that both antenatal and postnatal treatment so far as medical intervention was necessary called for specialist services led to the following:—

(Q. 19688–19689.) The British Medical Association have been here and have urged that every medical practitioner should, if he thinks fit, have a right to place his name on the midwifery panel. Are we to say if we adopted that recommendation we should be making a grave mistake?—I would say a very grave mistake.

You are prepared to put your opinion against that of the British Medical Association?—Yes.

(Q. 19697–19698–19699.) Is there anything left that the general practitioner can do with competence?—Yes, we are all prepared to agree with that.

We should be interested to hear it. So many people have told us there are so many things the general practitioner cannot do?—The general practitioner does deal with a normal amount of work connected with midwifery, all minor things, but I think everybody agrees that midwifery, directly it becomes abnormal at least, is a specialised subject, and they probably have not had either the time or the opportunity to concentrate upon that particular branch of the work.

National Union of Societies for Equal Citizenship.

(App. XCIX. and Q. 22975–23024.)

This Union, represented by Mrs. Hubback, is of opinion that no health insurance scheme is worthy of being called national if wives and children of the insured are excluded. They recommend the payment of allowances for the wives and children while the husband or father is unemployed owing to ill-health, the extension of medical benefit to dependants of insured persons, and the admission to voluntary insurance, after marriage, of women who have been insured workers.

Industrial Women's Organisations.

(App. C. and Q. 23025–23208.)

Dr. Marion Phillips, D.Sc., appeared for the Standing Joint Committee, which represents the whole of the organised working women of the country, whether in the political or industrial Labour movement or in coöperative organisations.

The Committee recommends extension of medical benefit to dependants, the raising of the income limit for non-manual workers from £250 to £350, and the extension of the scope of medical benefit to include every form of specialist service. The Committee further urges the adoption of the proposals of the Maternity Convention held at Washington in 1919, including the provision of adequate maintenance for mother and child.

(App. C. 27.) Such women should have the right to leave their employment six weeks before the expected birth of a child, and not be permitted to return until six weeks after, and the allowance should continue throughout the period.

The payment of what the Committee called Washington benefit—£1 a week for 12 weeks—would involve a net charge of about £1,000,000 per annum. The Committee suggests that the administration of the maternity and Washington benefits should be in the hands of the local maternity and child welfare committees. Dr. Phillips said that they were not prepared for any increase in the contributions of working women towards the cost of the new and increased benefits which were recommended. As to the panel system the witness said that it has worked fairly well, but there is a strong tendency towards an increase in the number of salaried full-time medical officers, and that it was a tendency to which the Committee saw no objection.

Amongst other points in the evidence was a suggestion that women should have a clear and full statement of their rights to sickness benefit in the antenatal period, and a statement that the witness thought that the objections of the British Medical Association to clinics was to some of the present uncomfortable clinics, where the patient has to wait for hours and get a very hurried and poor service very often in the end, and not to specialist clinics. Clinics should be supplemental to domiciliary treatment and not a substitute for it.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sterilisation of the Currency.

THE Academy of Medicine recently instructed a committee to inquire into the question of sterilising money and banknotes. Dr. Jules Renault, reporting the conclusions of this body, pointed out that sterilisation of money, as of all objects exposed to dirt, was theoretically desirable but at present impracticable. Fortunately, coins and notes, even the dirtiest, rarely carry pathogenic organisms; silver and bronze, indeed, have a considerable bactericidal action. Dr. Renault's researches showed that notes, if not sterile, are yet generally free from pathogenic organisms, a state of affairs probably due to the oxidation permitted by the porosity of the paper.

Alcoholism and Tuberculosis.

It has been stated that alcoholism favours tuberculosis. Dr. E. Arnould has recently studied the published statistics of this subject and concludes that more than half the fatal cases of tuberculosis in most countries occur in that section of the populace which, by reason of age, includes the fewest alcoholics. The incidence of alcoholism is always considerable in men and women between 30 and 60 years of age, although varying in different countries; the incidence of tuberculosis, on the other hand, is always low at this age and is fairly constant in all lands. In England and Germany statistics for the last 30 years show that the consumption of alcohol per head has not diminished, while the mortality from tuberculous disease has gone down 50 per cent. English statistics from 1890–1912 show no correspondence whatever between the alcoholic mortality and the tuberculosis mortality, either for any period or for any class or profession. In France the figures show that the consumption of alcohol is sometimes a little higher in rural districts than in towns and sometimes a little lower, while the tuberculosis mortality of the country is always lower than that of towns. There seems to be no statistical correspondence between the frequency of alcoholism and that of tuberculosis.

Mental Disease Among Soldiers.

Médecin Principal (Colonel) P. M. V. Chavigny, discussing[1] mental disease in the French Army, has given it as his opinion that in peace time there is no special form of mental disease peculiar to the army, but that the cases seen by the army specialist differ completely from those that come before the asylum physician. He makes the following points. In the first place military cases are generally seen quite early, and generally, also, they are so slight that they would have escaped notice in civil life, but the military environment, in which eccentricities are seen under a magnifying glass, makes the symptoms conspicuous. Slight as they are, they are of great importance, for their consequences may be serious to the patient in the military punishments which may mistakenly occur. Colonel Chavigny instances the stupid but well-to-do young man, who moves from one of his houses to another because, he alleges, he is bored everywhere. No one bothers about this vagary of his while he is a civilian, but if he acts so in the army he has become a deserter, with the gravest penalties due from him. In France every man is drafted into the army and must be utilised somewhere, if that is possible, or man-power is wasted. If he is not fit for the fighting line, a recent decree permits his being drafted into the auxiliary services where some occupation more suited to his intelligence may be found for him. After classifying these mildly insane cases, Colonel Chavigny advises that great pains should be taken to distinguish them from the merely idle or incompetent, but avoids the practical difficulty of suggesting the methods of diagnosis, and recommends great caution in classing any as malingerers before they have had a week's observation ("this prevents regrets"). He thinks the medical officer who will treat these cases successfully must be a good clinician, must seek to sympathise with the difficulties of his patients and desire to help them, must not judge their mental processes by his own high standard, nor must he think them cured when they are only silenced. "It is easy enough to empty one's wards, but that is not the aim." He also notes the difficulty of explaining these cases to a court-martial, which does not understand them, nor does it trust the expert. His article will well repay study.

Unfounded Protests.

Quite recently some 200 patients from the Municipal Tuberculosis Sanatorium at Bicêtre, Paris, formed a silent procession through the streets to protest against the bad quality and insufficiency of the food served to them; at their head was borne a placard bearing the inscription: "Defence committee for the interests of the tuberculous patients of Bicêtre." One well-known Paris journal decided to investigate the matter, and sent a representation to visit the institution at the invitation of the director of public relief. The representative came away full of praise for what he saw, and cheered by the reports several patients gave him of their well-being. No further protests, I understand, have been made.

International Anti-Tuberculosis Union.

The Executive Committee and the Council of the International Union against Tuberculosis at the last meeting adopted some interesting resolutions, to be presented to the next international conference in 1926. It was resolved that the following questions should be taken for discussion: (*a*) The part played by contagion in tuberculosis among adults (clinical subject); (*b*) anatomical structure of tubercle from histogenesis to cavity (biological subject); (*c*) tuberculosis and milk (social subject). Thursday, Sept. 30th, Friday, Oct. 1st, and Saturday, Oct. 2nd, 1926, are proposed for the next international conference at Washington, Dr. Theobald Smith, President of the American Association, to preside. A further resolution called attention to the need to intensify the organisation of occupational therapy, and the investigation of the relations between tuberculosis and school management.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Free State and the Medical Register.

UP to the moment of writing there has been no change in the position as regards the Medical Register, and the Government shows so far no sign of yielding to the pressure of public opinion in favour of maintaining the present arrangements. The newspapers have published many protests, not only from medical teachers and members of the medical profession, but from laymen who see the dangers of the policy adopted by the Government. Almost the entire bulk of the correspondence, and of the numerous interviews given to press representatives, has been in favour of continuing the control of the profession in the Free State by the General Council. One or two individual medical men have written in the contrary spirit, and a document in favour of the change has been published by a standing committee of University College, Galway, appointed to consider all matters of a medical nature affecting the College. They say:—

> "Control of Irish medical matters has been in the hands of the British Medical Council, on which Ireland has a minority representation. That the British Medical Council have worked in the interests of the profession is not disputed. The time has now arrived, however, when an Irish nation must control its own affairs, and this applies to medicine as to other matters. The action of the Government is the logical result of our present national status. The hardships which will accrue to Irish graduates when Irish medical men take charge of their own affairs has been unduly stressed. Australian and Canadian graduates may, without much difficulty, practise in England. We believe that the interests of young Irish medical men can also be protected."

This has been the only statement from any medical body in favour of the attitude of the Government. It has received two answers, written from very different angles. The first is given by "a prominent Dublin surgeon," who prefers to remain anonymous. He deals in some detail with the technical and legal difficulties involved in obtaining reciprocity or Colonial status. As regards reciprocity, the Dublin surgeon points out that if reciprocity be established, the mere fact of establishing such a relationship with the General Medical Council places the medical schools of Ireland again under its complete control.

As regards the technical mode of obtaining registrations on the Colonial List, the Dublin surgeon quotes the Medical Act of 1880 to show that—

> "the applicant must prove, to the satisfaction of the Registrar to the General Medical Council, that the diploma or diplomas through which he wishes to be placed on the Colonial Register were granted to him at a time when he was not domiciled in the United Kingdom, or in the course of a period of not less than *five years*, during the whole of which he resided outside the United Kingdom."

---

[1] Arch. de Médecine Militaire, May, 1925, p. 563.

He sums up his case as follows:—

> "The Free State Government cannot obtain reciprocal arrangements with England as regards the Colonial Register unless (1) they desire to be recognised as a British possession; (2) they wish to have their medical men tried by a 'foreign' tribunal, on which they have no representation; (3) they are content to wait until five years (one and a half years more) have passed since the setting up of the Free State."

Senator Oliver Gogarty, F.R.C.S.I., in a letter to the daily press, furnishes another, if indirect, answer to the Galway statement. He suggests that it is in the mind of the Government to turn the College of Galway into an institution in which a medical education will be given in the Gaelic tongue. As such a project might be difficult to carry out while medical education is under the control of the General Council, the Government first decides to abolish that control. Strange as such a suggestion appears, Senator Gogarty appears to write in all seriousness.

The "prominent Dublin surgeon" has rendered a service in stressing the difficulties that lie in the way of obtaining any reciprocal registering arrangement with Great Britain. Many of those who wrote to the papers took for granted that reciprocal arrangements were impossible, and contented themselves with pointing out the evils of an entirely independent and separate Register. Later controversy has therefore tended to focus more and more on the relative advantages and disadvantages of the Colonial List. In this connexion a point of some importance has emerged, in that it appears that the General Medical Council cannot register, either in the Colonial List or anywhere else, a Diploma in Public Health granted outside the United Kingdom.

The President and Vice-President of the Executive Council (Mr. Cosgrave and Mr. O'Higgins) have defended their position on the platform, the basis of their arguments being that the Irish nation must control its own affairs, and summing up the present problem as "a question as to the particular place on the Register on which the names of Free State doctors will appear." Two temporising measures have been suggested in the public press as a way out of the impasse: the first is that the Government should postpone the operation of its decision for a year by passing another temporary Act, concrete and definite arrangements for reciprocity being made in the available period; and the second, emanating from the Galway College, is to the effect that a provisional medical council be appointed, consisting of representatives of licensing bodies in the Free State, and that this body should discuss with the General Medical Council the future relations.

The President and Council of the Royal College of Surgeons in Ireland have summoned a public meeting of the profession for Tuesday, Sept. 8th, at 4.30 P.M., to consider the whole situation. The Council has passed a resolution approving of the attitude taken in the controversy by the President, Mr. R. C. B. Maunsell, and expressing its confidence in his judgment. It is wisely announced that no political discussion will be permitted at the meeting, which is for the education of the public on the questions at issue.

Poor-law Reform in Dublin.

The Commissioners in charge of the affairs of the Dublin Poor-law Union have under consideration a comprehensive scheme for the reform of Poor-law administration in Dublin. They hope to separate the several classes of inmates at present in the union, and to provide suitable treatment for each group. It is understood that the St. Vincent de Paul Society, a very powerful charitable organisation, is prepared to play an important part in assisting the Commissioners towards this end. The present intention is that the society shall take over a portion of the North Dublin Union premises for the reception of all able-bodied destitute classes with a view to reforming this particular class rather than housing them. With regard to the aged people, they will be handed over to some religious order and housed outside the union. It is possible that the old age pensions will be given to many of these people. Special treatment is to be provided for mental cases in surroundings which will give them every possible chance of a recovery. There are at present 400 such cases in the wards of the union and they are neither segregated nor treated in accordance with modern methods. They will be placed under the care of specially trained sisters, and will be paid for on a capitation basis. Consumptives will be provided for on similar lines. If all the arrangements projected are carried out, the only classes that will be received in the Dublin Union premises will be those needing medical or surgical treatment, and the buildings will be turned into a modern hospital. The scheme, it is claimed, will make for proper supervision and correction of the "ne'er-do-well," better treatment for the casually destitute person, up-to-date assistance for the mentally affected, proper classification for consumptives, with suitable surroundings, the provision of a home for the reception and training of crippled, deformed, and mentally defective children.

Northern Ireland: Vital Statistics.

During the quarter ended June 30th, 7414 births were registered in the 27 superintendent registrar's districts in Northern Ireland, this number being equivalent to an annual birth-rate of 23·2 per 1000 of the estimated population. The corresponding birth-rate for England and Wales for this quarter was 19·4 per 1000 and for Scotland 22·9. The deaths registered during the quarter numbered 4913, representing an annual rate of 15·3 per 1000; the corresponding death-rate in England and Wales was 11·7 per 1000 and in Scotland 13·0 per 1000. The population of Northern Ireland in the middle of 1925 is estimated to be 1,281,000, inclusive of military.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEKS ENDED (1) AUGUST 15TH AND (2) AUGUST 22ND, 1925.

1. *Notifications.*—The following cases of infectious disease were notified during the week ended August 15th: Small-pox, 34; scarlet fever, 1400; diphtheria, 700; enteric fever, 80; pneumonia, 441; puerperal fever, 54; cerebro-spinal fever, 9; acute poliomyelitis, 10; acute polio-encephalitis, 1; encephalitis lethargica, 35; continued fever, 1; dysentery, 11; ophthalmia neonatorum, 118. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 5 deaths from enteric fever, 18 from measles, 13 from scarlet fever, 37 from whooping-cough, 23 from influenza, and 13 from diphtheria. There were 136 deaths of children under 2 years from diarrhœa and enteritis, as compared with 108, 101, 64, 50, and 44 in the preceding weeks. In London itself there were 2 deaths from diphtheria, 3 from whooping-cough, and 5 from influenza.

2. *Notifications.*—The following cases of infectious disease were notified during the week ended August 22nd: Small-pox, 50; scarlet fever, 1330; diphtheria, 711; enteric fever, 88; pneumonia, 440; puerperal fever, 38; cerebro-spinal fever, 5; acute poliomyelitis, 10; acute polio-encephalitis, 1; encephalitis lethargica, 44; continued fever, 1; trench fever, 1; dysentery, 8; ophthalmia neonatorum, 112. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, 31 from measles, 9 from scarlet fever, 44 from whooping-cough, 20 from influenza, and 20 from diphtheria. There were 177 deaths of children under 2 years from diarrhœa and enteritis, as compared with 130, 108, 101, 64, and 50 in the preceding weeks. In London itself there were 4 deaths from diphtheria, 8 from whooping-cough, and 2 from influenza.

Dr. J. A. Mitchell, Secretary for Health and Chief Health Officer of the Union of South Africa, is taking three months' vacation in order to represent the Union of South Africa at the Conference of Empire delegates at the Ministry of Health, to be held in connexion with the proposed International Sanitary Convention.

"Audi alteram partem."

THE SUPPLY OF VACCINES TO PANEL PATIENTS.

To the Editor of THE LANCET.

SIR,—The letter of Dr. C. W. Cunnington in THE LANCET of August 22nd gives public expression to a question which I frequently hear asked by panel practitioners, and have wondered why more adequate arrangements are not made with pathologists for the supply of vaccines when required for panel patients.

In my work as pathologist I have *not* infrequently supplied either stock or autogenous vaccines for panel patients free of charge, for one or other of the following reasons. Either the case is so urgent that the clinical condition will not allow of the delay necessitated in obtaining official permission for the necessary vaccine preparation, or the panel practitioner obtains this help for his patients, which is not officially given; or when repayment is refused, as has happened, the pathologist has forgone remuneration for the work done on behalf of the panel service. I am sure my experience is not an isolated one. Most panel doctors are keen clinicians and want to give their patients not only the best therapeutic, but also prophylactic treatment, and are galled by the restrictions which limit adequate service being provided. The absence of these facilities for panel patients, which makes the occasional provision of gratuitous supplies necessary, introduces an obvious difficulty, for medical men hesitate or refuse to ask for the repetition of unremunerated assistance from colleagues except in very special circumstances, and therefore other cases are less adequately treated than might be.

It would not be difficult to arrange with the health insurance authorities for a standard rate for vaccines supplied for the treatment of panel patients and thus obviate such difficulties as your correspondent has encountered.—I am, Sir, yours faithfully,

E. CRONIN LOWE, M.B.E., M.B., B.S.

Southport, August 25th, 1925.

A PECULIAR SYMPTOM IN ENCEPHALITIS LETHARGICA.

To the Editor of THE LANCET.

SIR,—Since the mental sequelæ of encephalitis lethargica are attracting much attention at the present time, the following may be of interest to your readers.

Mrs. E. C., aged 25, married, a machinist by occupation, complained of insomnia of a fortnight's duration. She felt sleepy during the day and restless at night. On asking her to walk on tiptoe she staggered and said her "legs gave way." She had diplopia and consequently was unable to do her work. She complained of sore-throat and her voice was hoarse. Fine tremors of the hand could be detected on careful observation. The most interesting symptom consisted in the fact that she avoided travelling by omnibus and tramcar as it made her worse and uncomfortable, and consequently *preferred to walk* accompanied by her mother even a fairly long distance. Her pulse and temperature were normal.

It is difficult for me to offer a satisfactory explanation of the above symptoms, but no doubt neurologists will be able to elucidate them.

I am, Sir, yours faithfully,

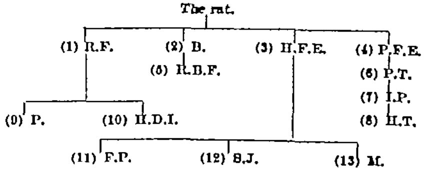
London, August 25th, 1925. J. D. DHRUV.

RAT-BORNE DISEASES.

To the Editor of THE LANCET.

SIR,—The Department of Agriculture S.S. and F.M.S. recently prepared an exhibit showing the damage done by rats to food and tropical produce for an agricultural exhibition held in Kuala Lumpur. The Institute for Medical Research was asked to collaborate by arranging a demonstration of the dangers of rats to public health, and the attached table of diseases of rats, which are communicable to man, was drawn up for the exhibit. As the table may be useful for other exhibitions and for propaganda during "rat weeks" I am forwarding a copy for publication.

Human Diseases Spread by Rats.



(1) R.F.—By the rat flea.
(2) B.—By biting.
(3) H.F.E.—By contaminating human food with excreta.
(4) P.F.E.—By contaminating pig's food with excreta.
(5) R.B.F.—Rat bite fever.
(6) P.T.—Pig trichinosis.
(7) I.P.—By eating imperfectly cooked infected pork.
(8) H.T.—Human trichinosis. (Trichina is a worm which, in its embryo stage, lives in the muscles.)
(9) P.—Plague.
(10) H.D.I.—Hymenolepis diminuta infection (a small tapeworm).
(11) F.P.—Food poisoning.
(12) S.J.—Spirochætal jaundice.
(13) M.—Melioidosis (a glanders-like disease).

I am, Sir, yours faithfully,

A. NEAVE KINGSBURY,
Pathologist, Institute for Medical Research,
Kuala Lumpur, Federated Malay States.

July 18th, 1925.

ASCARIS LUMBRICOIDES AND PIGS.

To the Editor of THE LANCET.

SIR,—I was very interested in the annotation in your issue for July 18th, *Ascaris lumbricoides* in Hertfordshire. Here in Port Said, for some reason not hitherto explained, about 90 per cent. of the Egyptian population (Port Said, European 13,000, Egyptian 87,000) are infected with ascaris, and it has always been a puzzle why this should be so as the rest of Egypt does not show such a high percentage for ascaris (about 4 per cent.). Your annotation probably puts us on to the origin of the trouble—pigs. In Port Said pigs are bred for the crews of the passing ships. The result is a vast herd of pigs feeding on the town rubbish dump near the destructors and, I suppose, hence the ascaris. The water-supply at Port Said is one of the purest and best in the world and is quite above suspicion.

I am, Sir, yours faithfully,

H. E. S. STIVEN, M.D. Camb.,
Principal Medical Officer, Government Hospital,
August 8th, 1925. Port Said, Egypt.

ALL SAINTS' HOSPITAL.

To the Editor of THE LANCET.

SIR,—May I draw your attention to the fact that in the Students' Number of THE LANCET there is no mention of this hospital among the supplementary hospitals giving courses of instruction.

Courses of instruction are given at the out-patient department, 49–57, Vauxhall Bridge-road, S.W. 1, on Monday, Wednesday, Thursday, and Saturday afternoons at 1.30, and on Monday, Wednesday, and Thursday evenings at 6.30; opportunities are afforded for the seeing of operations performed daily at the in-patient department at 91, Finchley-road, N.W. 8.

I am, Sir, yours faithfully,

ELIZABETH HART,
Assistant Secretary.

Vauxhall Bridge-road, S.W., August 29th, 1925.

Obituary.

JOHN FREDERICK GORDON DILL, O.B.E., M.D. Camb., M.R.C.S. Eng., M.R.C.P. Lond.,

CONSULTING PHYSICIAN TO THE ROYAL SUSSEX COUNTY HOSPITAL.

We announced last week the regretted death of Dr. J. F. Gordon Dill at the age of 66, which occurred at his residence in Hove on August 22nd.

Dr. Gordon Dill was the eldest son of the late Dr. Richard Dill, a well-known medical practitioner in Brighton and Hove, by his wife, the daughter of General Sir Charles Wale, K.C.B.—she only died in May last at the age of 101. Dr. Richard Dill had succeeded an uncle in practice at Brighton, thus making a long hereditary connexion.

John Gordon Dill was educated at Gonville and Caius College, Cambridge, and St. George's Hospital. At the University he graduated in honours in the Natural Science Tripos, and was well known also on the running-track and, perhaps especially, as a footballer under Association rules. He completed his medical education at St. George's Hospital, took the Cambridge M.B., and, after holding certain resident appointments, went to Paris to study under Charcot. At that time his inclination was towards entering into special practice in London, but on his return he decided to carry on his father's work at Brighton and Hove. Here he succeeded to and enlarged a prominent practice, while he was elected at the first opportunity upon the staff of the Royal Sussex County Hospital.

For the next 30 years Dill's name was associated with all medical movements in the town and county. He was at different times chairman of the Brighton Medical Association, president of the Sussex Medical Society, and physician to the Sussex Dental Hospital, as well as physician to the County Hospital, and in all his posts his wisely tolerant attitude, coupled with his energetic mind, made him early to see the places in which the organisation of the medical profession was weakest and enabled him to discern that the places were those in which the public interests had to be considered equally with those of the practitioner. He was an ardent champion of the right of the general practitioner to occupy an important place in all the national developments of medicine foreshadowed under the National Insurance scheme, while from his intimate acquaintance with hospital administration he could realise out of personal experience the fundamental troubles associated with the poverty of voluntary hospitals, the tragedy of bed shortage in the institutions coupled with their long waiting-lists, and the difficulties of dealing with hospital abuse—subjects upon all of which he wrote much and judiciously and on occasions spoke with great clearness. The concrete form which his energies finally took was the foundation of the Sussex Provident Scheme by which hospital benefits and additional medical services were to be brought economically within the reach of the proper subjects. This scheme, of which the full details have been published on several occasions in The Lancet, gained in the end, and after some criticism, the approval of the medical profession in the county of its origin, and soon began to attract attention elsewhere. It was a scheme designed to supply medical service which should debar no one from obtaining every accepted means of diagnosis and treatment, the essential aim being to supply a service which the patient could afford and which at the same time brought a fair remuneration to the doctors. The scheme rolled nine coöperating general and special hospitals together on a uniform basis, urgent cases being admitted to the hospitals as already arranged for, while other cases requiring operation or consultation were placed upon waiting-lists, such patients, however, taking no precedence of urgency cases. The consultation fees were drawn from a pool formed by deducting a percentage of the moneys allotted to each hospital, and it was Dill's hope that, if and when his scheme in Sussex could be proved successful, a similar plan would be applied to conditions ruling in other areas. His ideas took further practical shape in the foundation of the British Provident Association, when in 1921, with the assistance of Viscount Knutsford, Sir Arthur Stanley, Sir Alan Anderson, Lord Dawson, and Mr. McAdam Eccles, he set up the National Provident Scheme for hospital and additional services. This scheme, which during the intervening years has done excellent work and has developed into the British Provident Association as now known, owed its conception to his imaginative faculty. As secretary of the original scheme and of its permanent successor he gave of his time and energies without stint, and the results achieved are a proof of his sagacity as well as a justification of his enthusiasm for the welfare of his fellows. As far as Sussex is concerned, the last figures published showed that 26,500 members of the public were entitled to the benefits of the scheme, and that in 1924 over £5500 were paid through its channels to the hospitals for services rendered to the subscribers. It is understood that the figures for the first six months of the present year have an equally good or better promise.

In October last year Dill was compelled to undergo a serious operation from which at the time he made a successful recovery, but the relief proved only temporary, and the sad end was not unexpected by many of his friends.

Dr. Gordon Dill married Mary, daughter of the late Simon Martin, of the Indian Civil Service and son of the well-known consulting physician to the India Office, Sir Ronald Martin, by whom he had two sons. He leaves behind him the memory of an able and generous man whose talents as well as his personal charm had endeared him to a wide circle.

JAMES STEWART FOWLER, M.D., C.M., F.R.C.P. Edin.

Dr. J. Stewart Fowler, physician to the Royal Hospital for Sick Children, Edinburgh, died on August 24th in Elie, Fifeshire, at the age of 55. By his untimely death Edinburgh in particular and the medical profession in general has lost a valuable member.

James Stewart Fowler was the son of Dr. James Stewart Fowler, of Georgetown, Demerara, and was educated at the Edinburgh Academy. He received his professional training at Edinburgh University, where he graduated M.B., C.M. in 1892, taking in the same year the English double qualification. As a student he had a distinguished medical career, gaining honours on graduation, along with the Allan Fellowship, the Gunning Victoria Scholarship, and the McCunn Scholarship. He was keenly interested in the Royal Medical Society of Edinburgh, of which he was a Fellow and past president. After the usual hospital appointments in Edinburgh he went abroad to study in Vienna, and in 1899 took the M.D. Edin., being awarded a gold medal for his thesis. In 1895 he became a member of the Royal College of Physicians of Edinburgh and two years later obtained the Fellowship of the College with which he has been so closely associated ever since. Dr. Fowler practised as a physician, and was a sound authority on the diseases of childhood. He was senior physician to the Royal Hospital for Sick Children and University lecturer in diseases of children at that hospital, physician to the Chalmers Hospital, and honorary pediatrician to the Royal Maternity Hospital. Formerly he held posts as assistant physician to Leith Hospital and physician to the New Town Dispensary of Edinburgh. During the war he acted as temporary captain in the R.A.M.C., and was on active service with the forces in Salonica. In 1918 he was appointed secretary and registrar of the Royal College of Physicians of Edinburgh, which post he held up to the time of his death. He was a member of the Association of

Physicians of Great Britain and the Medico-Chirurgical Society and Pathological Club of Edinburgh, and took a great deal of interest in the proceedings of these societies.

Dr. Fowler made many valuable contributions to medical literature, and at the time of his death was joint editor of the *Edinburgh Medical Journal*. In 1899 he published, in joint authorship with Dr. G. Elder, "Diseases of Children: a Clinical Handbook," and in 1909 appeared his "Artificial Feeding of Infants." Both of these books have proved valuable works of reference. Among his contributions to various compilations and journals are the following: an article on Mumps in the Encyclopædia Medica (1901); Diseases of the Genito-Urinary System in Garrod, Batten, and Thursfield's Diseases of Children; Splenic Anæmia of Infancy, *Brit. Med. Jour.* (1902); Epidemic Cerebro-Spinal Meningitis, *Rev. Neurol. and Psychiatry* (1907); and, with Dr. Carnegie Dickson, Tuberculous Sclerosis, *Quart. Jour. Med.* (1910).

A colleague writes: "The unexpected suddenness of Dr. Fowler's death has come as a great shock to his many friends. Up till a few hours before the end he had been in his usual good health, and indeed on the morning of August 24th he had been on a boating expedition with his daughter and a friend. In the afternoon he felt ill, became unconscious, and passed away in the evening. As a skilled and sympathetic physician he was greatly loved, and his charm endeared him particularly to those very young children amongst whom he did the greater part of his work."

Dr. Fowler was married in 1902 to Edith, daughter of Mr. Philip Hudson, C.E., of Hyderabad, who predeceased him 11 months ago. He leaves one daughter.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. J. J. H. Rooney is placed on the Retd. List with the rank of Surg. Capt.

Surg. Comdrs. A. H. Joy to the *Pembroke* for R.N. Barracks, temp.; F. L. Smith to the *Furious*, on commg.; and S. F. Dudley to *Diomede*, on recommg. (lent to N.Z. Division). Surg. Lt.-Comdr. L. W. Gemmell to the *Comus*, on commg. Surg. *Lts.* E. B. Pollard to the *Columbine* for Port Edgar Base, temp.; S. Morrow to the *Furious*, on commg.; and S. G. Rainsford to *Pembroke* or R.N. Hospital, Chatham.

ROYAL NAVAL VOLUNTEER RESERVE.

J. Stephen, late Temp. Surg., and Proby. Surg. Lt. A. S. Bradlaw to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. F. W. W. Dawson retires on ret. pay.

Capt. R. P. Cormack is granted the temp. rank of Maj. whilst empld. as Dep. Asst. Dir. of Pathology.

Capt. W. E. Tyndall relinquishes the temp. rank of Maj. on ceasing to be empld. as a Dep. Asst. Dir. of Pathology.

Capt. D. C. Bowie is restd. to the Estabt.

Capt. G. O. Robinson is placed on the half-pay list on *account of ill-health.*

ARMY DENTAL CORPS.

Temp. Capt. A. S. Newton, Dental Surg., relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Qrmr. and Capt. F. C. Strike, having attained the age limit of liability to recall, ceases to belong to the T.A. Res. of Off., and retains his rank.

SUPPLEMENTARY RESERVE OF OFFICERS.

Capt. A. G. B. Duncan, late temp. Capt. R.A.M.C., to be Capt.

ROYAL AIR FORCE.

Flight *Lt. D. G.* Boddie is promoted to the rank of Squadron Leader.

Flight Lt. G. M. Mellor relinquishes his temporary commission on ceasing to be employed and is permitted to retain his rank.

Capt. A. B. H. Cole, Army Dental Corps, is granted a temporary commission as a Flight Lt. on attachment to the R.A.F. for a period of four years.

Flight Lt. J. Wren (Capt., Army Dental Corps) relinquishes his temporary commission on return to Army duty.

INDIA AND THE INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Cols. L. Hirsch (on account of ill-health), J. C. G. Kunhardt, and H. A. F. Knapton.

Capt. S. N. Hayes, Civil Surgeon, Dalhousie, is appointed Professor of Midwifery, King Edward Medical College, Lahore. Maj. E. W. O'G. Kirwin, Civil Surgeon, Murshidabad, is appointed to act as Superintendent, Central Medical Hospital, Berhampore, during the absence on deputation of Capt. J. E. Dhunjibhoy. Maj.-Gen. D. J. Collins, Deputy Director of Medical Services, Southern Command, officiates as Director of Medical Services in India, Army Headquarters, during the absence on leave of Maj.-Gen. O. L. Robinson. The services of Maj. J. A. S. Phillips, Assistant Director of Public Health (Malariology), United Provinces, are lent temporarily to the Government of Nepal *for malaria work.* Lt.-Col. Godfrey Tate, V.H.S., officiating Inspector-General of Civil Hospitals, Punjab, is appointed President of the Punjab Medical Council, vice Col. C. R. Bakhle, resigned.

The King has been pleased to give directions for the appointment of John Owen Shircore (Director of Medical and Sanitary Services) to be an Official Member of the Executive Council of the Tanganyika Territory.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—T. K. Clifford, Manchester; C. D. Cogswell, King's Coll. Hosp.; V. G. Crowley, Sydney; S. W. Cuff, St. Bart.'s Hosp.; A. L. Evans, London Hosp.; W. O. H. Evans, Bristol; T. H. Harrison, Sheffield; A. H. Henson, Charing Cross Hosp.; J. Herbert, Guy's Hosp.; E. P. Hyde, Manchester; A. B. Osbourne, St. Mary's Hosp.; W. Irving Pierce, Boston; F. Reynolds, Manchester; H. A. Sack, Middlesex Hosp.; G. H. Shanley, Durham; M. Schwartzman, Odessa and Middlesex Hosp.; and I. Waynik, Charing Cross Hosp.

Medicine.—C. D. Cogswell, King's Coll. Hosp.; W. Hinds, Durham; E. P. Hyde, Manchester; and M. V. Roberts, London Hosp.

Forensic Medicine.—O. Bastable, Leeds; E. P. Hyde, Manchester; E. J. Newman and M. V. Roberts, London Hosp.; and I. Waynik, Charing Cross Hosp.

Midwifery.—R. F. Ashkenny, Cambridge and London Hosp.; A. L. Evans, London Hosp.; W. Ivors, Manchester; E. H. Rampling, St. Thomas's Hosp.; M. V. Roberts, London Hosp.; and C. H. Spencer, Manchester.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: A. H. Henson, J. Herbert, W. Irving Pierce, A. B. Osbourne, and I. Waynik.

THE FELLOWSHIP OF MEDICINE.—The Fellowship of Medicine and Post-graduate Medical Association (1, Wimpole-street, W.) will provide an intensive course in general medicine, surgery, and the various special departments at the Westminster Hospital from Sept. 21st to Oct. 2nd from 10.30 A.M. to 5.30 P.M. each day. The fee for the course is 3 guineas or 2 guineas for either week. At the Infants Hospital a two weeks' comprehensive course dealing with the study of diseases of infants will be held from Sept. 7th. Three visits will be made to centres away from the hospital. The Seamen's Hospital will begin a five weeks' course in operative surgery from Sept. 7th. Classes will be held four times weekly, and the fee is fixed at £10 10s. In dermatology an afternoon course will be provided at Blackfriars Skin Hospital from Sept. 7th to 19th. A special demonstration of interesting cases will be given on Sept. 8th. The Royal Westminster Ophthalmic Hospital has arranged a three weeks' course from Sept. 7th. Clinical instruction will be given every afternoon, and special demonstrations three times weekly. From Sept. 21st to Oct. 3rd the Brompton Hospital provides a special course covering the various aspects of pulmonary disease by lecture, demonstration, &c. On four successive Wednesdays, beginning Sept. 23rd, Dr. C. B. Heald will give special *demonstrations on treatment* by electrotherapy at the Royal Free Hospital at 5.30 P.M., the course being designed for general practitioners. Full particulars and syllabuses of the courses, together with the Fellowship programme, may be obtained from the secretary.

British Mosquito Control Institute. — The opening of the new house of this Institute on Hayling Island by Sir Ronald Ross on Monday last was a public recognition of the valuable work done by a non-professional worker. Mr. John F. Marshall, the founder of the Institute, has devoted himself to the investigation and elimination of the mosquito from Hayling Island. From this nursery originate nearly all the mosquitoes that torment our coast towns in the late summer, and the general public owes a considerable degree of increased comfort on holiday to the efforts of Mr. Marshall and his fellow workers. The fourth report of the Institute describes the work undertaken, at a cost of £180, to clear the numerous breeding-places of the salt-water mosquito, *Ochlerotatus detritus*, and the fresh-water larvæ of *O. rusticus* and *Theobaldia annulata*. A valuable auxiliary corps was found in the "mosquito control class" of local school-children, who were taught how to identify and collect specimens of mosquitoes and larvæ. Many breeding-places have been located by the children. The original local work extended so rapidly that Mr. Marshall determined to erect a special building for research into the problems of mosquito control, and to inaugurate a "British Mosquito Control Institute." Many distinguished scientists have become members of its council and the opening ceremony was attended by a large party from the British Association. The Institute contains a demonstration museum, laboratory, drawing and record offices, photographic rooms, and a mechanical workshop, in addition to the well-equipped research rooms. Sir Ronald Ross, in his speech, said that 30 years ago, when he started work on malaria and mosquitoes in India, there was not a single satisfactory book or article on the mosquito. Now there was much knowledge, but energy to act upon the knowledge was still needed to carry on the work begun in Ismailia, Panama, and the Malay States. The ultimate aim must be to control all the dangerous and unpleasant pests that affect man, his crops, and his herds. He urged a great increase in the amount of money devoted to research. Colonel James, representing the Ministry of Health, seconded the vote of thanks to Mr. Marshall proposed by Mr. Tate Ryan, President of the Zoological Section of the British Association. Colonel James said that the success of public health administration was very largely due to the voluntary assistance received from public-spirited persons, adding that the Ministry of Health would watch Mr. Marshall's work with keen and helpful interest.

Royal Sanitary Institute.—The autumn course of lectures and demonstrations for sanitary officers commences at the Institute on Wednesday, Sept. 23rd. The course comprises the subjects scheduled for the examinations of the Institute and the Sanitary Inspectors' Examination Board (formed by the Institute and other bodies). On Friday, Oct. 2nd, a course of systematic practical training in the inspection of meat at a cattle market, &c., will be opened for meat and food inspectors. A detailed programme of the courses and full particulars may be obtained from Mr. E. White Wallis, F.S.S., director and secretary of the Institute, 90, Buckingham Palace-road, London, S.W. 1.

Insanity and Mental Deficiency in Scotland. The annual report of the Scottish Board of Control, which has just been issued, states that the number of insane and mentally defective persons under the Board's supervision on the first day of the present year was 20,850, of whom 18,398 were certified insane—almost exactly the same number as in the preceding year. Certified mental defectives have, however, increased from 2308 to 2452. The proportion of recoveries calculated on the admissions during the year was 33·4, which is 3·4 above the average of the previous five years. There was a substantial increase in the number of voluntary inmates. The Board express the hope that the contemplated scheme for the establishment of colonies for the adult mentally defective will reduce to a minimum the practice of placing of such patients in asylums.

Royal Medical Benevolent Fund.—At the last meeting of the Committee 54 cases were considered and £663 was voted to 43 applicants. The following is a summary of the new cases relieved :—

M.R.C.S., L.R.C.P., 1893, aged 59. Married, six children, aged 5 to 18 years. Eldest tea-planting in Ceylon at Rs.400 a month. The rest live at home and attend school. Income from practice and panel dispensary about £230 per annum. Rent and rates £66 per annum. Applicant was taken suddenly ill in July and was operated on for gangrenous bladder. Nursing home fees were paid by his colleagues in the profession, but it was discovered that the wife and family were without means. The Fund sent £10 at once.

Widow, aged 58, of L.R.C.P. Edin. who was a ship's surgeon and died abroad in 1923. Applicant has managed to keep herself and invalid sister on the little money left and by the sale of trinkets and jewellery. This being exhausted a large debt was accumulating for board and lodging when a doctor on the Committee of the Fund heard of the case and referred her to the Fund. An immediate grant of £5 was made for food. The Professional Classes Aid Council were asked to contribute towards the maintenance of the sister of the applicant, who is the unmarried daughter of a solicitor. A vote from them enabled the sister to be got away to be looked after as she is an invalid and crippled with rheumatoid arthritis, and our Guild found a post for the applicant and made a grant towards the debt outstanding for board and lodging. The Fund and Guild and Professional Classes Aid Council are working together to get the sister permanently looked after so that the applicant will be self-supporting.

Widow, aged 45, of L.R.C.P. Edin. who practised in Lancashire and died this year. She is left with three children, aged 6, 9, and 12, who are all at day school. After the practice was sold £500 was left and War Loan purchased. Applicant hopes to augment income by letting apartments. A report from the local branch of our Guild supported the application and the Fund voted £18 towards education and referred it to the Guild to consider a similar grant.

Widow, aged 36, of M.B. who practised in the Midlands and died in 1916. Applicant has been able to support herself and son, who is now 9 years of age, up to last November, when her mother died who looked after the boy whilst the applicant was at work. Help is asked for the child. The guardians have been applied to and a grant was made by them of 7*s.* 6*d.* a week for five weeks. The Fund voted £10 to a local doctor, who is interested in the case, to be administered for the benefit of the child.

M.R.C.S. Eng., aged 62, who is in practice and asks the Fund to help him while getting established. The practice is increasing, but he has only £42 in hand. Fund voted £40.

Widow, aged 54, of L.M.S.S.A. who practised as a ship's surgeon and died suddenly, leaving applicant and daughter, aged 17, totally unprovided for. Has been working as a servant but at present staying with friends. Voted £26 in six monthly instalments.

Subscriptions may be sent to Sir Charters Symonds, Hon. Treasurer, at 11, Chandos-street, Cavendish-square, London, W. 1.

Hospital Administration.—A three months' course of lectures and demonstrations will be given at the North-Western Hospital, Lawn-road, Hampstead, N.W., by the medical superintendent, Dr. E. W. Goodall, on Mondays and Thursdays, at 4.45 P.M., and alternate Saturdays at 10.30 A.M., beginning Oct. 1st. The fee is £4 4*s.*, and the course complies with the requirements of the revised regulations of the General Medical Council for the D.P.H. Further particulars may be obtained from the Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C. 4.

Post-Graduate Courses in Tuberculosis.—The following courses have been arranged by the Joint Tuberculosis Council: (1) A fortnight's course, Sept. 21st to Oct. 3rd, at Victoria Park (class limited to six members); (2) a course in non-pulmonary tuberculosis, Sept. 28th to Oct. 3rd, visiting Ascot, Carshalton, London Hospital, Royal College of Surgeons, All Saints' Hospital for Genito-Urinary Diseases, and Oxford (class limited to 30 members). Early application should be made to William Brand, acting hon. secretary, 19, Brunswick-square, S.E. 5, who will supply all further particulars (in addition to those published in The Lancet on August 22nd, p. 412).

The People's League of Health.—The Sims Woodhead series of constructive educational health lectures will commence on Friday, Oct. 9th, at 6 P.M., at the Regent-street Polytechnic, London, and will be continued on the following five Fridays at the same hour. Among those who have promised to lecture are: Sir Harry Baldwin, Dr. Leonard Hill, Prof. H. R. Kenwood, and Mr. E. B. Turner. At the conclusion of the series there will be an optional examination for those who have attended the series, and certificates will be issued by the Medical Council of the League. The fee for the series is 7*s.* 6*d.*, single lectures 1*s.* 6*d.* Tickets and further information regarding the lectures held may be obtained from Miss Olga Nethersole at 12, Stratford-place, London, W. 1.

Artificial Sunlight at Drury Lane Theatre. On August 26th Sir Alfred Fripp formally opened the artificial sunlight baths which have been installed at Drury Lane Theatre for the benefit of the company and staff. In opening the proceedings Sir Alfred Butt said that the directors believed that the greatest possible benefit would result from conserving the health of their employees, and the baths had been provided with this object. Every member of the company and staff could have a sunlight bath when desired, free of charge, provided the doctor approved. Sir Alfred Fripp gave a short address on the benefit of artificial sunlight and of the advantages of living as near to nature as possible; he said that he knew several prominent actors who had been greatly benefited by artificial sunlight baths, and congratulated the Drury Lane authorities on their generous action in providing this means for promoting the health of their staff and company. The installation is under the supervision of Dr. F. Howard Humphris, and Dr. Cecily Maude will be in charge at the theatre. The total radiation value is 100,000 candle-power and provides for about 60 baths per hour.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 7th, to SATURDAY, Sept. 12th.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars. Daily instruction in the out-patient department from 2.30 P.M. Special demonstration of cases on Tuesday.—INFANTS HOSPITAL, Vincent-square, S.W. Special Course. Lectures and demonstrations every afternoon. "Round Table" consultation on Friday, and on Saturday special visit to Model Pasteurising Plant.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross. Clinical instruction every afternoon from 2 o'clock with special demonstration three times a week.

Appointments.

CARON, N. B., M.B., Ch.B. Liverp., has been appointed Hon. Physician to the Royal Southern Hospital, Liverpool.

LAIRD, JEAN P., M.B., Ch.B. St. And., Junior Resident Medical Officer, East House and Hospital, Dundee.

THOMSON, I. S., Ch.B. Aberd., D.P.H. R.C.P.S. Eng., Assistant Medical Officer of Health and Tuberculosis Officer for Westminster.

Royal Infirmary, Sunderland: ROBINSON, W. V., B.M., B.Ch. Oxf., and HAMILTON, NORAH, M.B., B.S. Durh., Anæsthetists. MILNE, J., M.B., Ch.B., Deputy Anæsthetist. ROBINSON, V. P., B.M., B.Ch. Oxf., House Physician.

St. Paul's Eye Hospital, Liverpool: GORST, P. E., M.D. Liverp., M.R.C.S., L.R.C.P.; PLUMMER, F. C., M.D. Liverp.; and GRAVES, B., M.R.C.S., L.R.C.P., Hon. Surgeons. BICKERTON, H. R., M.B., B.Ch. Camb., M.R.C.S., L.R.C.P., D.O. Oxf., D.O.M.S. Lond.; HUGHES, E. N., L.R.C.P., M.R.C.S., D.O.M.S. Eng.; and MOORHOUSE, I. H., M.B., Ch.B. Liverp., Hon. Assistant Surgeons.

Westminster Hospital: DUNLOP, H. A., M.R.C.S., L.R.C.P., Lond., House Physician; and DAVIES, A. E. C., M.R.C.S., L.R.C.P. Lond., House Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: ANDERSON, D. L., M.B., Ch.B. Edin. (Hoddesdon, Hertford); CONYNGHAM, R. S., L.R.C.P. & S. Irel. (Snaith, West Riding); WILLIAMS, R. E., (Torpoint, Cornwall); and BOLTON, N. H. (Wrotham, Kent).

Vacancies.

For further information refer to the advertisement columns.

Ayr County Hospital.—Jun. H.S. £80.

Bradford Royal Infirmary. H.P. £150.

Brighton County Borough Sanatorium.—Res. M.O. £350.

Chiswick General Hospital.—Hon. Anæsthetist and Hon. Asst. Anæsthetist.

Denbigh County Council.—Asst. M.O. £600.

Dewsbury and District General Infirmary.—H.S. £200.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

Halifax Royal Infirmary.—Third H.S. At rate of £150.

Hampstead, New End Hospital.—Jun. Res. Asst. M.O. At rate of £150.

Hospital for Tropical Diseases, Endsleigh Gardens, N.W.—H.P. at rate of £110.

Hospital for Women, Soho-square, W.—Res. M.O. At rate of £100.

Lancaster County Mental Hospital.—Temp. Asst. M.O. 7 guineas weekly.

Lister Institute of Preventive Medicine, Chelsea Bridge-road, S.W.—Jenner Memorial Research Studentship. £250.

London School of Hygiene and Tropical Medicine, Endsleigh-gardens.—Director of Medical Entomology. £900.

Manchester and District Radium Institution.—Asst. Radiologist. £500.

Manchester Royal Children's Hospital, Pendlebury.—Asst. M.O. At rate of £150. Res. Surg. O. At rate of £80.

Manchester, St. Mary's Hospitals.—Three H.S.'s. Each at rate of £50.

Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—Anæsthetist.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—H.P.'s, H.S.'s, &c. Each at rate of £50.

Norwich, Norfolk and Norwich Hospital.—H.S. £150.

Nottingham Children's Hospital.—Res. H.P. and Res. H.S. Each at rate of £150.

Pharmacological Laboratories of the Pharmaceutical Society of Great Britain.—Director. £1200.

Prince of Wales's General Hospital, Tottenham, N.—H.S., Spec. H.S., and H.P. Each at rate of £150. Also Jun. H.S. and Jun. H.P. At rate of £110.

Queen Mary's Hospital for the East End, Stratford, E.—Cas. O.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—H.S., H.P., and Cas. H.S. Each at rate of £100.

Radium Institute, 16, Riding House-street.—Cancer Research Worker. £500.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal National Orthopædic Hospital.—H.S. At rate of £150.

Royal Northern Hospital, Holloway, N.—M.O. to Out-patients. At rate of £125. Also H.S. and Obstet. H.S. Each at rate of £70.

St. Bartholomew's Hospital and College.—Res. Asst. Phys.-Accoucheur and Demonstrator of Pract. Midwifery.

Salford County Borough.—Asst. Clin. Tub. O. £600.

Salford Royal Hospital.—Res. M.O. and H.S. At rate of £175 and £125 respectively. Also Radiologist. £300.

Singapore, Straits Settlements.—Two Asst. Health Officers. $7200.

Southern Rhodesia Government Public Health Dept.—Dentist. £650.

West London Hospital, Hammersmith-road, W.—H.P. and Two H.S.'s. Each at rate of £100.

Whipp's Cross Hospital, Leytonstone.—Res. Asst. M.O. £350.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment for a Certifying Factory Surgeon at Boxhill, Sussex.

Births, Marriages, and Deaths.

BIRTHS.

BERRY.—On August 30th, at Glenthorne, Park-avenue, Watford, the wife of D. H. Berry, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

BROWN.—On August 19th, at Bassett-crescent, Southampton, the wife of Dr. A. W. Brown, of a daughter.

GRAHAM-HODGSON.—On August 17th, at Grey Lodge, Chislehurst, the wife of Dr. Graham-Hodgson, of a daughter.

HAULTAIN.—On August 30th, at Walker-street, Edinburgh, the wife of W. F. Theodore Haultain, F.R.C.S.E., of a son.

RAMMELL.—On August 17th, at Swaffham, Norfolk, the wife of Dr. J. Rammell, of a daughter.

THOMPSON.—On August 23rd, at Eastbourne House, Devizes, the wife of James Thompson, F.R.C.S., of a daughter.

MARRIAGES.

BROADBRIDGE—HEAD.—On August 20th, at St. Marylebone Parish Church, Harold George Broadbridge, M.B., B.S. Lond., to Enid Muriel, only daughter of the late Mr. and Mrs. Robert Head.

CANNING—TURTON.—On August 10th, at St. Saviour's, W., Henry George Richmond Canning, L.R.C.P., M.R.C.S., L.D.S. Eng., to Ruth Helen Gwenyth, only daughter of Mr. and Mrs. Turton, of Tintagel, Cornwall.

COWELL—SMITH.—On August 22nd, at Bideford Church, Dr. S. J. Cowell, to May Penelope, eldest daughter of Mr. and Mrs. Cecil Smith, of Link House, Westward Ho!

McGRATH—TYNDALL.—On August 12th, at Blackrock, Co. Dublin, William M. McGrath, M.B., B.Ch., B.A.O., Cane Hill Mental Hospital, Coulsdon, Surrey, to Eileen, elder daughter of the late Mr. J. P. Tyndall, "Farmleigh," Stillorgan, Co. Dublin, and Mrs. Tyndall, Eaton-square, Monkstown, Co. Dublin.

OVERTON—BROMAN.—On August 26th, at the Savoy Chapel, Squadron-Leader R. S. Overton, M.R.C.S. Eng., L.R.C.P. Lond., R.A.F., of Sutton Lodge, Sutton, Surrey, to Justine Leontine ("Jean") Broman, of Oslo, Norway.

WHITAKER—WAITE.—On August 29th, at Knutsford, Cheshire, Sydney Morgan Whitaker, M.D. Brux., M.R.C.S. Eng., L.R.C.P. Lond., of St. Helier, Jersey, to Hilda Mary, widow of Lieut. J. Thorp Waite, 5th East Kent Regiment (The Buffs), and elder daughter of the late Frederic Smith, of Dunham Lawn, Bowdon, Cheshire.

DEATHS.

ACKLAND.—On August 17th, at The Circus, Bath, Donald Ackland, M.R.C.S., L.R.C.P. Lond., aged 50.

BRAMWELL.—On August 26th, at Corfe, Taunton, Herbert Bramwell, M.D., F.R.C.S. Edin., M.R.C.S. Eng., late Lieut.-Colonel, Gloucestershire Hussars, T.D., son of the late John Byrom Bramwell, of Tynemouth, Northumberland, aged 62.

BURROWES.—On August 16th, at Lomain, Looe, Cornwall, Henry Ambrose Burrowes, M.D., aged 60.

DILL.—On August 22nd, John Frederick Gordon Dill, M.D., Denmark Villas, Hove, aged 66 years.

DUNBAR.—On August 25th, suddenly, at Oakfield-road, Clifton, Bristol, Eliza L. Walker Dunbar, M.D. Zurich, L.R.C.P.I. and L.M., younger daughter of the late Alexander Walker, M.D., H.E.I.C.S., in her 80th year.

FOWLER.—On August 24th, at Broehead, Fife, suddenly, James Stewart Fowler, M.D., F.R.C.P. Edin., of Northumberland-street, Edinburgh, aged 54.

LANGDON-DOWN.—On August 19th, at Dixland, Teddington, Percival Langdon Langdon-Down, aged 57.

MARSHALL.—On August 24th, at Hove, John James de Zouche Marshall, V.D., L.R.C.S.I., L.M., L.A.H. Dub., Lieut.-Colonel (retired) R.A.M.C., T., aged 79.

ODELL.—On August 21st, at Ferndale, Torquay, William Odell, M.D., F.R.C.S., aged 74.

WALES.—On August 18th, at Downham Market, Thomas Garneys Wales, M.R.C.S., in his 93rd year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

HOSPITAL ORGANISATION.

To those concerned with the present problem of meeting the hospital needs of this country the series of handbooks on Hospital Organisation, Construction, and Management, published by the Macmillan Company of New York, should prove instructive. The first of the series, by Joseph J. Weber, M.A., editor of the "Modern Hospital," deals in a general way with the hospital field as we find it to-day, and some very striking figures are quoted, showing the rapid progress which has been made in the United States since 1873. In 1873 there were only 149 hospitals in the United States; at the beginning of 1923 there were in the United States and its possessions 7095 hospitals and sanatoriums, with a total patient bed capacity of 792,069. The ratio of hospital beds to the population is very striking; in New York City the actual hospital beds available in January, 1923, was five beds to every 1000 of population. The factors influencing the ratio of beds to the population are fully discussed, and it is noted that there is a very direct bearing between the number of hospital beds required and the housing conditions of the community. In estimating the hospital needs, one might calculate on 75 per cent. of the beds being utilised through the year. Mr. Weber indicates the procedure to be adopted by a board of trustees in the organisation of a hospital, and the various steps to be taken to arrive at the best results. The second volume is by Frank E. Chapman, director, Mount Sinai Hospital, Cleveland, and deals in detail with general administration, laying emphasis on the centralisation of administration. Various diagrams and tables are given showing how this is carried out in different parts of America, and the methods adopted in some hospitals are given in great detail. Many useful hints are given, which are worthy of careful consideration.

THE FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—The committee venture to ask you to allow them to make a very urgent appeal again for *subscriptions and* donations for the Factory Girls' Country Holiday Fund. Some of those who are hoping to go away during the next few weeks have never slept out of London. Our funds are very low, and we fear that in any case many will be disappointed of their little holiday this summer.

The need for this brief rest and change is probably more urgent than ever before. Trade depression has resulted in the girls becoming the main support of hundreds of families, which but for their earnings would be on the verge of starvation. The general standard of comfort in the average home is lower than it has been for many years, and the health of the community in the crowded and airless factory districts of London has deteriorated considerably. Nor is it possible for the girls to contribute as much towards a holiday as they have done in former years. Good food, rest, and fresh air for a short time would make it possible for many to continue their work through the coming winter, who might otherwise break down under the strain and privation they have had to bear for so many months. The short holiday will give them fresh hope and courage.

Subscriptions and donations will be thankfully received and acknowledged by Miss Canney, 75, Lamb's Conduit-street, W.C. 1.

We are, Sir, yours faithfully,

ALBERTA SANDWICH.
MARY SCHARLIEB.
MARY ST. HELIER.
A. F. LONDIN.
JOHN KENSINGTON.

FRANK LLOYD.
J. H. HERTZ,
Chief Rabbi.
J. F. GREEN,
Chairman of the Executive
Committee.

August 27th, 1925.

HEALTH RESORTS IN GERMANY.

THERE has recently been published in Berlin a large and comprehensive directory, compiled from official sources, of the various spas, watering-places, and health resorts of Germany. The compilers of this *Reichs Bäder Adressbuch* state that the publication is the first of its kind, and as a work of reference the sphere of its utility should be very extensive. The book is, of course, methodically constructed, the resorts being described and illustrated alphabetically in three sections, while an appendix deals with the large towns. A table of resorts grouped geographically follows the preface, and a general index completes the volume. Of particular interest to medical men is the index, in which the spas are grouped according to the disease conditions for which they are specially suited. The cost of the *Adressbuch*, containing 980 quarto pages, is 9.50 Rentenmarks.

MEDICAL MEN AND DEATH CERTIFICATES.

IN the House of Commons recently Sir Gerald Strickland asked the Home Secretary whether he was aware that it was not unusual for certificates of death to be signed by doctors without previously viewing the body after death and on the hearsay evidence of others; and whether he was prepared to propose legislation which would make it incumbent on doctors who signed death certificates to add thereto that they had ascertained to the best of their ability that death had actually occurred and was not merely apparent. This is a very old question, Mr. Neville Chamberlain replied, assuming reference to a certificate which the medical practitioner in attendance on a deceased person in his last illness is required by law to give, "stating to the best of his knowledge and belief the cause of death." He pointed out that the first part of the question gave the present position, but with regard to the latter part of the question he said that the whole subject is under consideration. The matter of death certification has waited for new legislation too long; some term ought to be put to the delay.

CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.

THIS society has now on its register over 5500 masseurs and masseuses, the majority of whom are qualified to administer treatment by massage, remedial exercises, and medical electricity under medical directions. The society was incorporated by Royal Charter in 1920, and its efforts towards the establishment and maintenance of a careful training in this important ancillary branch of the healing art have done much to secure a worthy place in the ancillary ranks of medicine for the masseur and the masseuse. Admission to the register is obtained by examination. Independent examinations are provided and supervised in London, at various centres in the provinces, in Scotland, and in Ireland, the subjects of examination extending to anatomy, physiology, pathology, massage, remedial exercises, and medical electricity. Many well-known medical men and women, specialists in these subjects, act as examiners, and no member can receive a certificate until a qualified medical practitioner has been satisfied with the candidate's proficiency. The society's register shows that members are now practising throughout the United Kingdom, in the Colonies, and elsewhere. Lists of members practising in any particular district or a copy of the register may be obtained from the secretary of the society, 157, Great Portland-place, London, W. 1.

COUGHING EPIDEMIC IN MILLS.

A MYSTERIOUS epidemic of coughing has broken out among weavers in Burnley mills. It makes them so ill that they have to cease work, and others who have taken their places are similarly affected. Operatives when they return to the mill are again affected. This is the third time such an outbreak has occurred in Burnley mills, the last occurrence being 12 years ago. It has been decided to close the mills for a week, when all suspected apparatus will be removed. In one of the previous outbreaks the cause was believed to be mildew in weft, but it appears that this outbreak was not due to the weft.

CIVIL SERVICE BONUS.

THE Minister of Health announces, on information received from the Lords Commissioners of H.M. Treasury, that the review on Sept. 1st, 1925, of Civil Service bonus will be on the basis of an average cost of living figure of 75, that is, on the same basis as obtained during the six months commencing Sept. 1st, 1924.

MEDICAL EDUCATION IN MISSOURI.

"IF Governor Baker is far-sighted, he will purge Missouri at once of the noisome mess," is the comment of the *Journal of the American Medical Association* on certain curious positions in medical and public relations that have arisen in the State. "Noisome" is hardly too violent an adjective if the suggestions in our contemporary are warranted, for we have stories of money received to influence the Secretary of the State Board of Health, of appointments to the State Penal Board in return for political services given by persons whose records are shadowed by political intrigue, and names are employed throughout. The position reached is, that the Board of Health of the State, having issued an ultimatum that they would resign, are now embarrassed by finding that, if they are loyal to their ultimatum, they will leave the field to the Governor and to one surviving member, when new men can be appointed to cover up the whole situation. The use of strong language by our contemporary appears warranted.

Principles
OF
TREATMENT BY MANIPULATION
OF SOME CHRONIC DISORDERS OF THE KNEE-JOINT FOLLOWING INJURY.

By A. G. TIMBRELL FISHER, M.C.,
F.R.C.S. Eng.,
LATE HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON (WITH CHARGE OF OUT-PATIENTS) AND JOINT LECTURER ON OPERATIVE SURGERY, DREADNOUGHT HOSPITAL.

An attempt will be made in this paper to point out the underlying pathology of those chronic affections of the knee-joint following injury that may be cured or markedly alleviated by that valuable and often brilliant therapeutic measure, manipulation.

The medical historian of the future will have to record that our profession has greatly neglected this important subject and has shown too often a tendency to proscribe rest when movement has in reality been indicated, adhering to the dictum "rest inflamed structures" when the cause of the chronic inflammation has been some intra-articular condition which a lifetime of rest or its concomitants, plaster, Scott's dressing, and strapping would not cure, but which could often have been rapidly cured by special manipulative methods. The fact must be faced that the bone-setter has been curing multitudes of cases by movement, many of which have previously been ordered too prolonged rest by our profession, even by its most eminent members, and that by our often faulty methods we are largely responsible for his very existence. It is churlish and dishonourable under these circumstances to throw exaggerated emphasis on the dangers of bone-setting, real though they be, and to minimise the good work for humanity that some of the best of these unqualified practitioners have performed.

Wharton Hood wrote more than 50 years ago:—

> "The belief in the great value of rest in such cases may be regarded as a tradition handed down from the time of Sir Astley Cooper, who said, 'In no cases, after injury, should the patient be allowed to exercise the parts as usual, until all pain has ceased and the part has nearly regained its original form.'"

Hilton and H. O. Thomas perpetuated this teaching. Although half a century has passed since these words were written, the tradition is still firmly rooted in certain circles.

There are a large number of different lesions affecting the knee-joint which may occur after trauma. It is proposed to enumerate first examples of the after-effects of an exceedingly common form of injury—viz., sprain of the internal lateral ligament, although much will apply to other sprains of this joint. Afterwards we shall shortly discuss the after-effects of contusions, lesions of the semilunar cartilages, toxic or infective synovitis, chronic arthritis, combined cases, and functional cases.

Space will not permit here of any description of manipulative technique, and for this reason a number of illustrative cases are also omitted. Further details will be found in a forthcoming publication.

SPRAINS OF INTERNAL LATERAL LIGAMENT: PREVENTION OF ADHESIONS.

Much that follows in this section applies also to sprains of other ligaments of the knee such as the external lateral.

The general treatment of such sprains, and the prevention of adhesions resulting from synovitis following a sprain of a lateral ligament, can be summed up in a few words—viz., "Rest from all undue strain of the damaged ligament combined with early movement of the joint." At first sight this maxim may seem contradictory, but in reality this is not the case. Rest from weight-bearing and excessive use permits healing to proceed, *but early movements, at first of but short* duration, prevent the formation of adhesions. The principle of early movement, admirable though it be, is not sufficient, for unless we aim at early movement *through its full range*, adhesions may yet develop and give rise to much subsequent trouble.

Let us attempt to illustrate the principle of the prevention of adhesions by a concrete example, viz.:—

Treatment of a Case of Synovitis of the Knee following a Sprain of the Internal Lateral Ligament.

Rest in bed or on a couch is enjoined at first. This is combined with a firm compression bandage over a thick layer of wool, which should completely surround the joint and extend for some little way upwards into the thigh and downwards into the leg, leaving a small fringe of wool above and below uncovered by the bandage. No splint should ever be used, but the joint slightly flexed over a pillow, for experience has shown this to be the position of greatest ease. Rest from weight-bearing must be enjoined as long as the synovial effusion persists. From the very first the bandage is removed daily and gentle massage (effleurage), electrical stimulation of the quadriceps, and movements may be instituted, for these, added to the elastic compression, play an important part in the absorption of the intra-articular effusion and prevent muscular wasting. Each day the movements are increased. In about a week in marked cases, or considerably less in minor cases, effusion will have subsided, and it should be our aim to have obtained full movements by this time.

There is now no objection to weight-bearing, provided strain upon the recently damaged ligament be eliminated, and this can usually be ensured by the simple device of reinforcing the inner sides of the sole and heel by a wedge-shaped piece of leather ¼ in. in thickness, or in severe cases rotation and abduction may be prevented by the temporary use of a knee-cage which permits flexion and extension. For a short period, and especially if there is any tendency to swelling occurring after exercise, a compression bandage should be worn during the day. This, however, should be dispensed with as soon as possible, as it tends to interfere with the development of the thigh muscles. As this swelling is often due to loss of tone of the thigh muscles, every effort should be made to remedy this by re-education.

Treatment of Chronic Cases.—It has already been mentioned that in many of these cases we are faced with a set of conditions constituting a vicious circle. The sprain has given rise to synovitis; this causes reflex wasting of the thigh, and the resulting laxity of the capsule still further predisposes to minor traumata of the synovial membrane and delayed absorption of synovial fluid. It should be pointed out that the tenderness over the internal lateral ligament is due to the presence of scar tissue, which may be present not only in the ligament itself, but in the synovial membrane lining its deep surface which, indeed, may be adherent to the scar. Now this scar tissue when stretched gives rise to a sensation of acute pain and a reaction in the joint, and hence the recurrent attacks of pain and effusion after exercise. The presence of scar tissue in excess is the *fons et origo* of the group of symptoms, and the great principle of treatment is to deal with this and subsequently to concentrate upon the treatment of the resulting and concomitant conditions. The latter are sufficient in themselves to give rise to serious trouble and a continuance of symptoms after the internal lateral ligament has ceased to be a source of trouble per se. The ideal treatment of the original lesion, as we have seen, is so to direct Nature's efforts that the scar formed is not in excess—neither should it cause any interference with movement, but neither should it be unduly stretched. By early movements there can be no doubt that we may prevent the adhesion of the synovial membrane to the scar in the internal lateral ligament. When adhesions have actually developed which persist after a fair trial has been given of gymnastic exercises, the vicious circle may be broken and the patient put on the high road to recovery by manipulation. In some slight cases this measure is all that is necessary, but in neglected cases the after-treatment is of great importance and must follow two important lines.

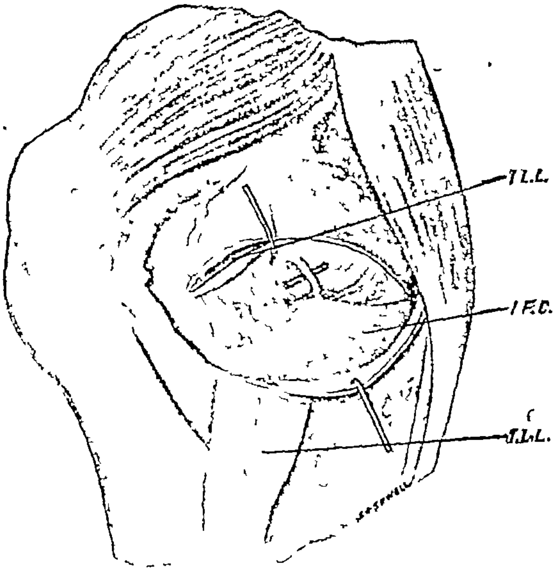
(1) The increased range of movement obtained by manipulation must be preserved, and the ground gained consolidated by the patient voluntarily exercising the joint through the increased range at regular intervals, commencing almost immediately.

(2) The wasted thigh muscles must be made to recover their tone and bulk by re-education. It will be then noted that the lateral mobility hitherto present will usually disappear. In some minor cases the adhesions may be gradually stretched and full movement restored by gymnastic exercises; this process is, however, longer, more tedious, and less reliable than manipulation under anæsthesia.

Pathology of Cure by Manipulation in Cases of Neglected Sprain.—The internal lateral ligament is stretched on full extension but relaxed during flexion. It is difficult therefore to explain the actual mechanical limitation of flexion on the supposition of the presence of scar tissue in the ligament itself. To appreciate better the pathological condition present the anatomy of the region should be recalled.

Surgical Anatomy.—The relationships of the various parts may be seen from a reference to Figs. 1 and 2. It will be seen that beneath the upper part of the internal lateral ligament near its femoral attachment is a synovial pocket or recess which forms part of the synovial reflection from the femoral condyle to the capsule. Normally the two layers of synovial membrane are in contact, and the internal lateral ligament is in contact with the outer synovial layer. In ruptures, either partial or complete, of the long portion of the internal lateral ligament, it is clear that the synovial membrane must participate therein, and that, if the joint be left at rest, the two opposed layers of synovial membrane must become glued together by inflammatory exudate which may become organised with the formation of a definite adhesion. Furthermore, the outer layer of synovial membrane must become adherent by fibrous tissue to the scar in the ligament.

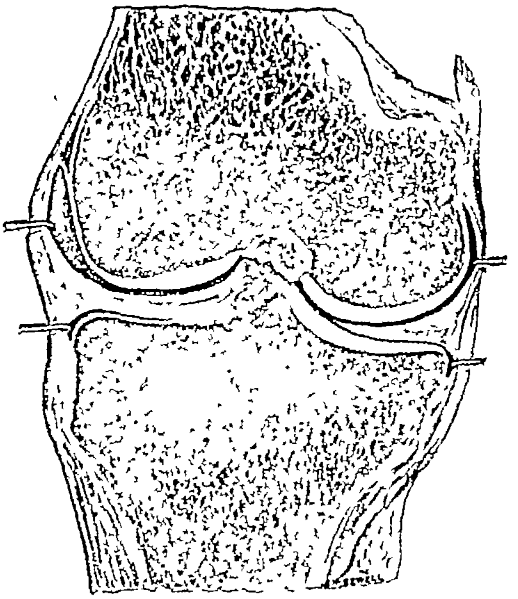
FIG. 1.



Dissection of inner aspect of knee-joint showing synovial pocket beneath internal lateral ligament and adjacent part of capsule. The rod is inserted beneath an adhesion. I.L L = internal lateral ligament. I.F.C. = internal femoral condyle.

There is no greater contributory factor in the formation of these adhesions than prolonged treatment by complete rest, plaster, Scott's dressing, and strapping. In fact, the adhesion of the two opposed layers of synovial membrane is made almost certain thereby. Another shallow synovial pocket is also present beneath the attached margin of the semilunar, where the synovial membrane lines the deep surface of the coronary ligament and is reflected from it to the margin of the tibial condyle (Fig. 2). It is probable that after ruptures of the deep fibres of the internal lateral ligament adhesions are particularly liable to form at this site, giving rise to persistent tenderness. The tenderness at this site is often quite erroneously thought to indicate a displaced semilunar cartilage, and when, as so often happens, a complete cure results from manipulation in this type of case, the bone-setter has often obtained the credit for curing a displaced cartilage of long standing.

FIG. 2.



Coronal section through anterior part of knee-joint showing synovial pockets above and below semilunar cartilages.

CONTUSIONS OF THE KNEE-JOINT.

The most characteristic symptom of contusion is that the pain and tenderness are localised to the affected area and remain thus localised for a considerable period, and in some cases a troublesome form of periostitis ensues. Contusions, like sprains, are very liable to be followed by synovitis with effusion, and much that has already been said concerning the general pathology of adhesions in cases of sprain applies also to adhesions following contusion. There is, however, a great tendency in the latter cases for the adhesions to be more generalised, and although they may occur almost anywhere, they tend to be more marked in the front and lower part of the joint, in the region of the infrapatellar pad of fat and its processes, and at the lateral synovial reflections. The adhesions may be of great delicacy and yet potent of much trouble, or of a somewhat extensive nature. Localised tenderness is often present, with limitation of some particular movement or movements. In this connexion the movements of the patella laterally and the rotatory and "screw-home" movements should always be tested. The pathology of this type of case is described more fully in the author's book.[1]

CHRONIC OR RECURRENT LESIONS OF THE SEMILUNAR CARTILAGES: THEIR DIFFERENTIAL DIAGNOSIS AND MANIPULATIVE TREATMENT.

We are not here concerned with the question of manipulation in original displacements of the semilunar cartilage, although it may be mentioned that there is no evidence that early movements after reduction, provided rotation be avoided, are less *efficacious in bringing about union than the long* period of immobilisation that is often ordered, which is apt to lead to the pernicious after-effects of adhesions and wasting

---

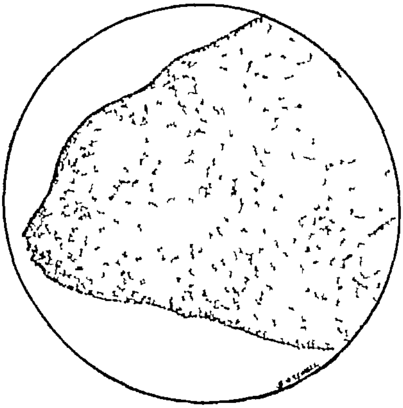
[1] Internal Derangements of the Knee Joint; their Pathology and Treatment by Modern Methods. H. K. Lewis and Co.

The author has investigated the problem of repair in the semilunar cartilages experimentally, and has also examined microscopic sections of fractured semilunar cartilages removed at operation at various intervals from the original injury These investigations all point to the fact that repair is sluggish in the menisci (Figs. 3 and 4)

It must never be forgotten that in most cases a lesion of the internal semilunar cartilage is in essence a complication of a severe sprain of, at any rate, the deep fibres of the corresponding lateral ligament. There will therefore be a somewhat similar history to that of sprain and a certain similarity in the points of tenderness In many chronic cartilage lesions however, tenderness is completely absent Protrusion of the fractured cartilage outwards, although mentioned in many text books, is, in the author's opinion, excessively rare, but a peculiar "rumble" or "snap" on flexion and extension is almost pathognomonic of a torn meniscus.

The most characteristic feature about a recurrent *lesion of a semilunar cartilage is the history* of one or more attacks of true mechanical locking, which may be momentary or last until reduced by manipulation, which often occurs with an audible snap Very frequently mechanical locking occurs at the *original* accident, and thereafter attacks of sudden giving way associated with a loud report, crack, or snap rather than true locking, *or*, on the other hand, locking may not occur at first, but on subsequent occasions.

FIG 3.



Transverse section of fractured surface of semilunar cartilage of long standing. The surface is smooth and in places covered by an endothelial layer

One of the most striking features in the differential diagnosis is the excellent and often *detailed* history that the patient gives. He or she will even demonstrate the exact position of the limb which produces the 'locking' A young baronet in whose knee-joint the author found tears of both semilunars told him that any *turning movement* caused a report "like a double-barrelled gun, and down he fell. The author has frequently felt justified in exploring a knee-joint purely on such an accurate and careful history and in the complete absence of any physical *signs, and has almost invariably found in such cases* a torn cartilage True mechanical locking must, of course, be very carefully distinguished from limitation of movement due to synovial effusion and pain, which in the original injury are of later onset, *and from other* forms of mechanical locking as may occur with loose body or certain injuries to the tibial spine.

In some cases the symptoms of semilunar derangement are less typical For instance, it is obvious that if merely a slight tear is present this will not bring about true locking, and the symptoms will approximate more to those of sprain of the corresponding lateral ligament, and often there will be a complaint of giving way rather than of true locking In the author's opinion it is impossible to diagnose this type from sprain, and it should be treated as the latter at first Suspicions should be aroused if the symptoms of the sprain persist over an unusually long period, when no limitation of movement suggesting adhesions is present, when all other causes have been excluded (a radiogram being never omitted), and when manipulation followed by a course of re-education of the wasted muscles fails to cure the condition In such a case exploratory arthrotomy is certainly justifiable, preferably by the author's patella-displacing approach, through which all the structures in the anterior compartment of the joint may be exposed to vision

To sum up, our sheet anchor in diagnosis between *sprain of the deep fibres of the lateral* ligament alone and a lesion of the corresponding meniscus must be an accurate and painstaking history The position of maximum tenderness helps in some cases, but is often fallacious There is a type of case in which, in the present state of our knowledge, having ruled out of court by a complete investigation other forms of internal derangement, it is impossible to say whether a patient is suffering from the sequelæ of a sprain or whether he has one of the less common types of lesion of the internal meniscus In my opinion the practitioner should proceed upon the following lines in this difficult type of case He should explain the position to his patient and advise a manipulation first, for this is simple free from risk, and often succeeds In the event of failure, exploratory operation should then be advised.

Underlying Pathology of Manipulation in Lesions of the Semilunar Cartilages

It may be stated at once that in the author's *opinion* although manipulation in cases of neglected sprain or contusion associated with adhesions is a most valuable therapeutic measure, this method of treatment is not quite so satisfactory in recurrent lesions of the semilunar cartilages *Cases of apparent* cure occur, especially when too long an interval has not elapsed since the primary lesion, but in some the benefit is of a temporary nature. This fact depends upon the physiology of repair in the semilunar cartilages. Repair is at best sluggish, and when the fractured surfaces have become smooth and endothelialised (Fig 3) the repair is even more slow, but if accurate apposition is maintained is quite possible

A fact of fundamental importance in this connexion is that the commonest lesion of a semilunar cartilage is a definite tear which usually takes the form of a complete longitudinal tear or "bucket-handle" type of lesion (Figs 4 and 5), and the characteristic symptoms of the semilunar derangement are due to the behaviour of the fractured portion of cartilage It is most important to remember that it is quite possible for the inner torn portion, if narrow, *to occupy certain* abnormal positions without giving rise to any *permanent* locking or limitation of movement or, indeed, to any physical signs whatsoever For instance, the *inner portion may* be in the intercondylar space between the crucial ligament and the femoral condyle and it is only when some sudden turning movement causes the portion of cartilage to slip outwards that giving way or locking occurs

If, however, the inner portion is broad, it cannot be in such a position without causing mechanical interference with extension. These facts have all been confirmed on several occasions at operations by the author. This frequent absence of mechanical interference with movement, even when a fractured portion of a semilunar occupies some abnormal position, has hitherto been largely overlooked, but seems to have been known to the bone-setter. It seems fairly clear that what the bone-setter achieves in this type of case is to *cause the displaced fragment to retrace its steps, when, in a certain proportion of cases, sufficient repair may take place between the two fragments to prevent recurrence.* The chances of repair must clearly depend upon the age of the lesion. In time the fractured surfaces become smooth and rounded, and in these late cases the chances of repair are proportionately lessened. Again, in cases of multiple tear the chances of permanent recovery by manipulation are very slight. My operation findings, moreover, convince me that in certain cases in which manipulation has been performed, the fractured portion of the cartilage has been forced into the intercondylar region between the femoral condyle and crucial ligament, where from its position it has given rise to continuance of symptoms, and by slipping periodically between the femoral condyle and the tibia has caused attacks of giving-way or actual locking.

To sum up, the commonest lesion of a semilunar cartilage is a definite tear, and most commonly the complete longitudinal tear or "bucket-handle" type (Figs. 4 and 5). At the original accident the inner torn portion is usually dislocated into the interior of the joint, where, being fixed at first between the femoral and tibial condyles, it gives rise to a mechanical block to extension.

By manipulation two things may happen: (1) The displaced portion may retrace its steps and, provided rotary movements are avoided for some time, repair will probably take place. (2) The displaced portion may be forced still further into the interior of the joint, when the mechanical locking is released, but symptoms become recurrent. In these recurrent cases the fractured portion may yet be made to retrace its steps by manipulation, and repair by fibrous tissue gradually occurs.

There is a group of conditions to which I particularly desire to draw attention that interfere with the normal "screw-home" movement of the inner femoral condyle, and which are particularly amenable to treatment by manipulation. These are: (*a*) Minor displacements of the anterior half of the internal semilunar cartilage due to stretching or tearing of the coronary attachment; (*b*) inflammatory induration of the semilunar process of the infrapatellar pad of fat with adhesions in connexion with the latter process.

(*a*) *Minor Displacements of the Anterior Horn of the Internal Semilunar.*

To refer briefly to the anatomy of this important region. If a transverse section be made through the knee-joint at the level of the semilunar cartilages, it will be seen that the internal semilunar, in addition to the attachment to the true capsule, is firmly adherent to the deep fibres of the internal lateral ligament, and behind this to the aponeurotic layer. The anterior half of the cartilage, however, is separated from the aponeurotic layer by a well-marked interval filled with loose fatty tissue, and the periphery is attached to the margin of the internal tibial condyle by a portion of the true capsule, known as the coronary ligament. A weak mechanical site therefore exists at this spot where the mobile anterior half meets the more fixed posterior half, opposite the level of the internal lateral ligament. A sudden twist inwards of the femur upon the fixed tibia with the knee slightly flexed may, without causing a definite tear of the cartilage or of its anterior attachment, cause a partial rupture of the coronary attachment and a minor displacement, not sufficient to cause obvious locking, but a feeling of discomfort on full extension, which may be limited by a few degrees.

(*b*) *The Semilunar Extensions of the Infrapatellar Pad of Fat.*

In the investigation of 100 formalin-hardened knee-joints I found that the anterior one-third of the internal semilunar cartilage is usually protected by a process of the infrapatellar pad of fat, upon which the important screw-home movement of the internal femoral condyle occurs at the termination of extension; and this process is frequently injured, either alone, or simultaneously with injury of the anterior end of the internal semilunar. Although the process is so important clinically, it has not been considered worthy of a name by the anatomists, although it is often wrongly called the inner alar pad. Possibly "semilunar process" or "pad" might be a better name. In a large number of cases in which it is considered that a lesion of the cartilage is present, it is really this process which is at fault. A lesion of the process may be followed by the formation of adhesions between it and the cartilage, or some other adjacent structure. It seems clear, however, that it is in this group of conditions that manipulation is a valuable therapeutic measure.

We must never overlook another very important fact before deciding that any case has been cured by manipulation—viz., that long intervals which in some cases may amount to many years may normally exist between attacks of "locking," and therefore we can never be logically certain that we have really effected a permanent cure in any given case. If a definite recurrence occurs after a manipulation, operation should in most cases be advised, although occasionally a second manipulation may succeed.

MANIPULATION IN TOXIC OR INFECTIVE SYNOVITIS AND CHRONIC ARTHRITIS.

This condition is very liable to follow any of the aforementioned injuries of the knee in persons past the meridian of life. It is not proposed to discuss its pathology here as the author has previously discussed it in various publications.

The remarks already made concerning the misapplication of rest apply with redoubled force to this group of conditions, in which the articular surfaces are but little affected and the disease is principally situated in the synovial membrane. This leads in most cases to a certain amount of painful limitation of movement due to intra- and peri-articular adhesions.

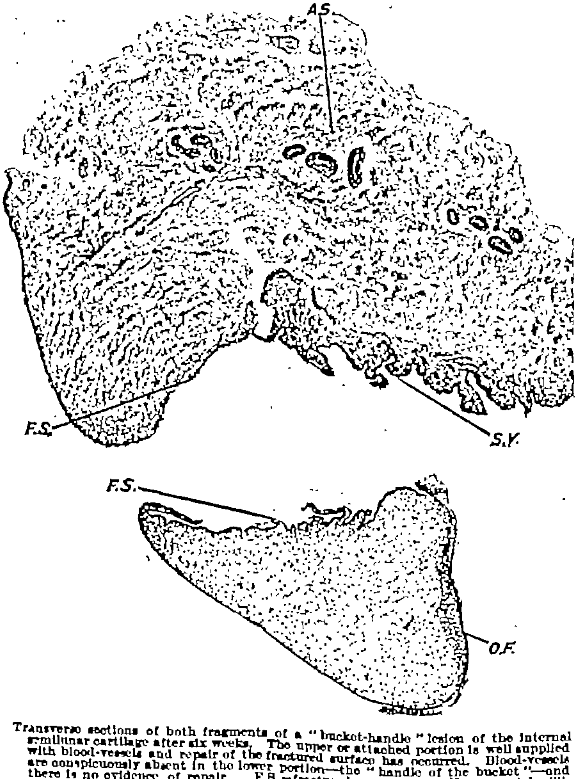
Unfortunately, the symptoms due to the presence of these adhesions are often mistaken for some progressive disease, and what not infrequently happens is that the patient receives every conceivable form of medical treatment and wanders from one spa to another with the knee fixed in an orthopædic apparatus, and the movement for which the joint is clamouring i withheld. When such a joint is fixed it is physic logically placed at the greatest disadvantage fo combating any smouldering infection that may b present, for the circulation not only of blood but o lymph, and the secretion and absorption of the synovi fluid, depend largely upon regular movement. Whe complete rest is enjoined, the formation of synovi fluid is very markedly diminished, and the amour of fresh blood-bearing phagocytes and antibodies i reduced to a minimum.

One of the principal complaints in this disease is c stiffness and discomfort of the joint after the night rest or after sitting still for some time, but whic disappears after exercise. Over-exertion is, of cours to be most carefully avoided, but the practice c completely immobilising the joint in this type of cas is contrary to the dictates of reason or even of commo sense.

In chronic arthritis of what the author ha designated the chondro-osseous and mixed types i which the articular surfaces are also involved, th principle of preserving movement, if this is possibl should be maintained. In these chronic cases Natu is endeavouring in a remarkable way to form a ne joint, and the patient, if possessed of the necessary determination, can assist the process very materially.

The author has endeavoured to show that a fundamental feature is degeneration of the central poorly nourished part of the articular cartilage and proliferation, which is often compensatory, of the lateral better-nourished portions whereby chondro-osteophytes are formed. Nature makes good the loss of the central part of the articular cartilage by sclerosis and eburnation of the subarticular bone, and the chondro-osteophytes extend the articular surface. If regular movements through complete range are maintained from the first the following benefits result. 1. Contracture of scar tissue, both intra- and extra-articular, and painful limitation of movement is prevented. 2. Mechanical obstruction of movement by osteophytes is also prevented. 3. The process of eburnation is materially assisted. 4. Muscle tone is preserved. 5. The nutrition of the joint structures is maintained.

FIG. 4.

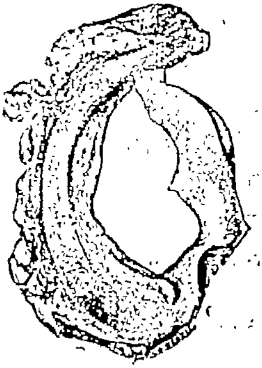


Transverse sections of both fragments of a "bucket-handle" lesion of the internal semilunar cartilage after six weeks. The upper or attached portion is well supplied with blood-vessels and repair of the fractured surface has occurred. Blood-vessels are conspicuously absent in the lower portion—the "handle of the bucket"—and there is no evidence of repair. F.S.=fractured surface. S.V.=synovial villi. O.F.=outer fragment. A.S.=attached surface.

Many persons are able to lead active lives when all the evidence points to the fact that the articular cartilage in the affected joint has been largely destroyed. In cases in which these principles have been neglected, an effort should always be made in the first place to restore full movement by manipulation. It is often assumed, and this applies particularly to the hip-joint, that if marked osteophytes are present nothing short of open operation can be of any avail. It is surprising to find in many of these cases that the limitation of movement actually due to osteophytes is much less than one would imagine and that by manipulation a marked increase of movement may be obtained.

A strong tendency exists in many quarters to the formation of a fixed joint by excision in these cases. In my opinion this is very rarely necessary and should only be performed as a last resource. It is a tragedy to consider how often this operation is quite unnecessarily performed. A fixed joint is a considerable disability in itself; for instance, an ankylosed hip in good position is usually assessed at 60 or 70 per cent. disablement. Cases have come to my notice on which the operation has been performed on young persons in which it was quite clear that sufficient had not been done to secure a movable joint.

FIG. 5.



Typical example of complete longitudinal tear ("bucket-handle" lesion) of internal semilunar cartilage, which constitutes by far the commonest pathological type of lesion.

Mixed Cases.

In certain cases of sprain or cartilage lesion the clinical picture may be greatly complicated by the supervention of a toxic synovitis or chronic arthritis, both of which may be localised or generalised, and in other cases the damaged ligament appears to be picked out by circulating toxins and the picture complicated. This is particularly liable to occur in persons past the meridian of life, and suspicions are aroused by three factors: (a) the existence of "rheumatic" symptoms elsewhere or a history of them; (b) when recovery from a sprain is unusually prolonged; (c) the presence in the patient of some focus of toxic absorption.

Functional Disorders of the Knee-joint following Injury.

This is a large and important subject to which it is impossible to do justice in a short paper, and attention is merely drawn to a few special points which are sometimes overlooked.

1. An injury associated with marked mental shock, such as a railway or motor-car accident in which the knee is injured, is particularly liable to give rise to a neurosis in an individual of a nervous temperament. There is no surgeon of great experience who has not at some time been puzzled or misled by a functional condition of the knee.
2. A purely functional condition may occur from the first, or more frequently the condition is superadded upon some such condition as a slight degree of chronic synovitis or arthritis. The unwary or inexperienced may overlook the functional element, and consider that the symptoms and signs betoken a much more marked degree of arthritis than is actually present.
3. Quite apart from the question of injury it must be remembered that a functional element is very frequently quite a marked feature in chronic arthritis in both sexes. These are the cases of "rheumatoid arthritis" of many years' standing which are cured by "faith-healers."
4. In an early functional case, if spasm be abolished by anæsthesia, full movement can be obtained readily. If, however, the condition is of long standing, actual adaptive shortening of ligaments and periarticular structures occurs. This is, of course, more liable to occur if the condition has been superimposed upon a slight degree of chronic synovitis or arthritis.
5. Even in primarily functional cases swelling of the joint may occur probably from the general loss of tone of the thigh muscles and impaired absorption of synovial fluid. It may then be a moot point whether the functional condition is primary or secondary.
6. Manipulation is by far the most effective therapeutic measure in these functional cases owing to the powerful suggestion of the anæsthetic. Treatment by suggestion should, however, precede and immediately follow the anæsthetic, and be carried on for some weeks or months subsequently.
7. The after-treatment is often of more importance than the manipulation itself, and not only the surgeon, but everyone with whom the patent comes in contact, must endeavour to convince the patient that he or she is now cured.
8. The prognosis in these cases depends upon the time that the condition has been present, in cases of long standing the prognosis is less hopeful. Even more, perhaps, depends upon that indefinable but all-important attribute, the personality of the surgeon who performs the manipulation.

In conclusion, much work remains to be done before bone-setting is placed upon a scientific basis. Let us hope that for the honour of our profession workers will not be lacking, so that we shall eventually arrive at the truth.

SOME
Practical Considerations
IN THE CONSERVATIVE TREATMENT OF FRACTURES OF THE PELVIS AND LOWER EXTREMITY.

A Course of Four Lectures delivered for the University of London at St. Bartholomew's Hospital

BY SIR WILLIAM I. DE COURCY WHEELER,
M.D. DUB., F.R.C.S. IREL.,
PAST PRESIDENT, ROYAL COLLEGE OF SURGEONS IN IRELAND.

LECTURE IV.*

Fractures about the Knee-joint.—(*Continued.*)

Fractures of the Patella.

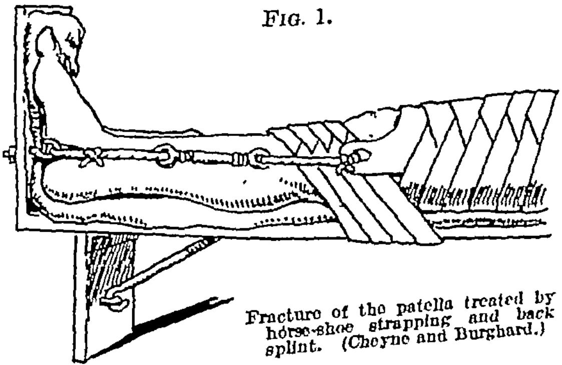
THERE are certain cardinal points in connexion with fractures of the patella to be borne in mind. (1) In comminuted and longitudinal fractures conservative treatment is followed by bony union. (2) Transverse fractures should be treated by operation, but nevertheless an excellent functional result may follow with wide separation of the fragments. I have an intimate friend who fractured his patella about 30 years ago. He has wide separation of the fragments, but walks without a limp and without inconvenience, and takes strenuous exercise. (3) Operation followed by bony union is not always followed by a good functional result. (4) If the fracture occurs near the ligamentum patellæ, the knee-joint may not be opened, as the synovial membrane is reflected from the posterior surface of the patella some distance from the inferior tip of the bone. (5) Circumstances will arise when a fractured patella cannot be sutured under favourable conditions, and if the conditions are not ideal the attempt should not be made.

The first part of conservative treatment is to get rid of the effusion. To accomplish this, the limb should be elevated to relax the quadriceps extensor muscle and a tight bandage applied over several layers of wool. A practical way of helping absorption is suggested by Scudder:

> Two slightly moistened bath or carriage sponges are allowed to dry under pressure sufficient to flatten them. These are placed upon each side of the knee and over it, and are held by a few turns of a roller bandage. Cold water is then poured over the whole. As the sponges absorb the water they enlarge, causing equable and firm pressure on the knee, thus very materially hindering the accumulation of fluid and favouring its absorption. This dressing is repeated every day. When the effusion has disappeared a calliper splint can be applied, in the manner recommended by Jones. The calliper splint should be worn for about two months. Full flexion of the knee should then be restrained for a time by a knee-cage, to prevent gradual separation of the fragments.

There are many other methods employed, the "Middlesex Hospital" method being one of the best.

FIG. 1.



Fracture of the patella treated by horse-shoe strapping and back splint. (Cheyne and Burghard.)

Fig. 1 shows the upper fragment pulled down by horse-shoe shaped strapping to the foot-piece of back splint.

Operative Treatment.

In dealing with fractures of the patella by operatio we must be certain that the largest synovial cavit in the body is not exposed to the slightest ris of accidental infection. If a disaster occurs th knee will be partially or completely stiff. If partially the joint will be painful. Amputation of the thigh may become necessary in severe sepsis.

I have never performed any complicated operation such as plating or bone grafting, for fractured patella. A simple procedure is adopted:

> The joint is opened between the two fragments by curved or transverse incision. Clots and torn tissues ar cleared away from between the fragments. Doyen's o Reverdin's needle is passed through the quadriceps tendon i close contact to the upper margin of the patella. The needl is threaded with a fine loop of aluminium bronze wire an pulled through. The loop is cut and the needle is passe through the ligamentum patellæ in close contact to the lowe

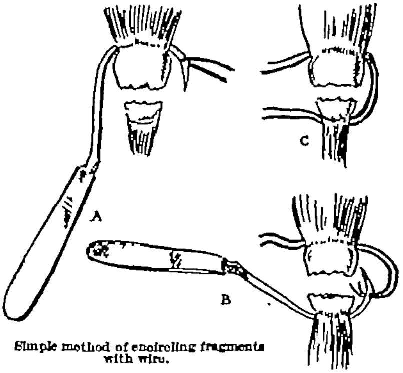
---

* Lectures I., II., and III. appeared in THE LANCET of August 15th and 22nd and Sept. 5th respectively.

border of the lower fragment; the double wire is again threaded and pulled through. The ends of the wire are now twisted and tied tightly, bringing the two fragments into apposition by an encircling suture. The torn portions of the capsule and aponeurosis are stitched with a few points of catgut. The wound is dressed. No splint is applied, and the patient is allowed to practise voluntary movements from the beginning, so far as he is able to do so without pain. (Fig. 2, A, B, and C.)

I have found that these cases walk about with the help of a stick after a fortnight or three weeks, and that they return in two or three months with bony union and full movement of the joint.

FIG 2.



Simple method of encircling fragments with wire.

FRACTURES OF THE TIBIA.

Fractures of one or both condyles of the tibia occur either as the result of distortion or from direct violence, just as in the case of fractures of the condyles of the femur. They may or may not involve the joint, and the treatment is identical with that already outlined for fractures of the femoral condyle.

Fractures of the spine of the tibia, associated with rupture of the crucial ligaments, are not very uncommon. Jones mentions 25 cases. I have seen them from time to time at Mercer's Hospital as the result of severe violence. In one case the tibia was completely dislocated backwards. The knee-joint is immobilised in plaster of Paris, and neither active nor passive movements allowed until two months have elapsed. Then very gradual and gentle movements are allowed. A Thomas walking calliper may be substituted for plaster fixation. If, following this treatment, movements are restricted as a result of a bony block produced by a detached spine uniting by callus, the knee-joint must be exposed by longitudinal division of the patella, and the bony block removed.

OSGOOD'S OR SCHLATTER'S DISEASE.

The condition is sometimes spoken of as "Rugby knee." Pain and tenderness rapidly disappear under rest treatment, and a knee cage should be worn limiting flexion of the knee and the activities of the patient for some months. The epiphyseal strain may exist without much difference between the X ray appearance of the normal and abnormal bone.

FRACTURES OF THE TIBIA AND FIBULA (UPPER THIRD).

These injuries have received but scant attention, owing to the ease with which treatment can be carried out. The treatment is identical with that of fractures of the condyles of the femur, and consists in manipulating the fragments, while an assistant is fixing the extension tapes to the end of a Thomas splint. Loops of bandages are applied to control any lateral or antero-posterior deviations.

FRACTURES OF THE LOWER THIRD.

It is when we come to the common broken leg, that is to say, an oblique or spiral fracture of the lower end of the tibia, with a fracture of the fibula at a slightly higher level, that real difficulties in conservative treatment arise. Fractures of the tibia alone, or of the fibula alone, are already splinted by the uninjured bone. A little extension and manipulation will easily correct any slight displacement, and the limb can be encased in plaster of Paris from the foot to above the knee. At the end of six weeks, weight may be borne on a walking calliper.

Fracture of the fibula alone, without displacement of the foot, is only of interest because the diagnosis may be missed. *Special attention* should be paid to the ecchymosis which appears some time after the injury, and often extends up along the line of the fibula. The same ecchymosis arises in all fractures, including fractures of the base of the skull. In doubtful cases of fracture of the long bones without displacement, ecchymosis following the line of a bone should put the practitioner on guard. If extensive ecchymosis coexists with a point of maximum tenderness, a *fracture is almost certainly present.*

These remarks apply to fractures of the fibula, both in its upper and lower thirds.

Walking may be allowed when it is possible to do so without causing pain. No form of splintage is necessary. When the fracture is near the ankle-joint it is wise to wear an outside iron, or to raise the inner side of the boot, so as to anticipate any possibility of valgus deformity occurring under the strain of weight-bearing.

Treatment of Fractures of the Lower Third of the Tibia and Fibula.

With the oblique and spiral fracture I have had more difficulty and seen more bad results than in any other fracture of the lower limb. Anyone with experience in setting these fractures knows that manual extension of the foot is very unsatisfactory. If it is a recent case, and it is decided to fix the limb in plaster from the foot to well above the knee, the hands of the assistant get in the way at every turn of the lower part of the bandage, and displacements occur. It is impossible for an assistant to keep up sufficient extension and to keep the fragments in alignment during the application and setting of the plaster in a difficult case. On the other hand, there is not sufficient of the limb below the fracture to apply adhesive strapping for fixation to the end of a Thomas splint.

Sinclair's foot-piece and glue, as a means of putting extension on the lower fragments, has given satisfaction to many surgeons, but, after failures by this and other methods, I have adopted the following plans sometimes singly and sometimes in combination.

1. In certain cases, with the patient under an anæsthetic, and the knee held flexed by an assistant, extension and manipulation of the foot readily reduces the shortening, and corrects the alignment. If steadily held, there is no great tendency to recurrent displacement of the fragments, and the assistant experiences little difficulty while the limb is immobilised in plaster

2. The deformity can only be reduced with difficulty, and the slightest move of the foot brings about slipping of the fragments. In such cases the sectional plaster of Paris method, as recommended by Cockerill, is useful. (Fig. 3.) I have a case so treated at present in Mercer's Hospital. By the sectional plaster method is meant that separate plaster casings are applied and allowed to set above and below the injury. The injured area remains exposed and free for manipulation. The first section of plaster should be applied from just above the fracture to the middle of the thigh, with the knee slightly flexed. The second plaster encases the foot. The two sections are allowed to set, and the plaster is trimmed at the edges. The foot is now fully dorsiflexed in slight inversion by the assistant, while the surgeon unites the two plasters by a few turns of a third plaster bandage. If more extension is required than can be obtained comfortably by manual traction, a clove hitch is placed round the foot encased in its plaster and attached

Functional Disorders of the Knee-joint following Injury.

This is a large and important subject to which it is impossible to do justice in a short paper, and attention is merely drawn to a few special points which are sometimes overlooked.

1. An injury associated with marked mental shock, such as a railway or motor-car accident in which the knee is injured, is particularly liable to give rise to a neurosis in an individual of a nervous temperament. There is no surgeon of great experience who has not at some time been puzzled or misled by a functional condition of the knee.
2. A purely functional condition may occur from the first, or more frequently the condition is superadded upon some such condition as a slight degree of chronic synovitis or arthritis. The unwary or inexperienced may overlook the functional element, and consider that the symptoms and signs betoken a much more marked degree of arthritis than is actually present.
3. Quite apart from the question of injury it must be remembered that a functional element is very frequently quite a marked feature in chronic arthritis in both sexes. These are the cases of "rheumatoid arthiritis" of many years' standing which are cured by "faith-healers."
4. In an early functional case, if spasm be abolished by anæsthesia, full movement can be obtained readily. If, however, the condition is of long standing, actual adaptive shortening of ligaments and periarticular structures occurs. This is, of course, more liable to occur if the condition has been superimposed upon a slight degree of chronic synovitis or arthritis.
5. Even in primarily functional cases swelling of the joint may occur probably from the general loss of tone of the thigh muscles and impaired absorption of synovial fluid. It may then be a moot point whether the functional condition is primary or secondary.
6. Manipulation is by far the most effective therapeutic measure in these functional cases owing to the powerful suggestion of the anæsthetic. Treatment by suggestion should, however, precede and immediately follow the anæsthetic, and be carried on for some weeks or months subsequently.
7. The after-treatment is often of more importance than the manipulation itself, and not only the surgeon, but everyone with whom the patent comes in contact, must endeavour to convince the patient that he or she is now cured.
8. The prognosis in these cases depends upon the time that the condition has been present, in cases of long standing the prognosis is less hopeful. Even more, perhaps, depends upon that indefinable but all-important attribute, the personality of the surgeon who performs the manipulation.

In conclusion, much work remains to be done before bone-setting is placed upon a scientific basis. Let us hope that for the honour of our profession workers will not be lacking, so that we shall eventually arrive at the truth.

SOME

Practical Considerations

IN THE CONSERVATIVE TREATMENT OF FRACTURES OF THE PELVIS AND LOWER EXTREMITY.

A Course of Four Lectures delivered for the University of London at St. Bartholomew's Hospital

By Sir WILLIAM I. de COURCY WHEELER,
M.D. Dub., F.R.C.S. Irel.,
PAST PRESIDENT, ROYAL COLLEGE OF SURGEONS IN IRELAND.

LECTURE IV.*

Fractures About the Knee-joint.—(*Continued.*)

Fractures of the Patella.

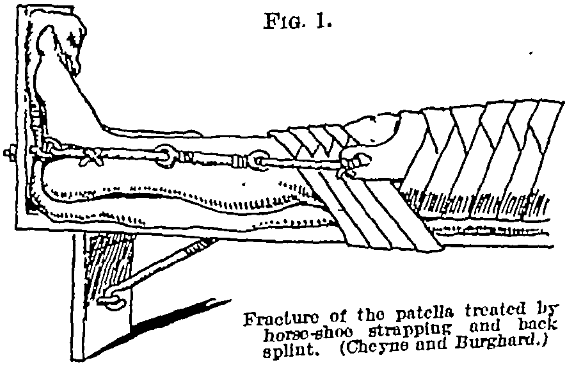
There are certain cardinal points in connexion with fractures of the patella to be borne in mind. (1) In comminuted and longitudinal fractures conservative treatment is followed by bony union. (2) Transverse fractures should be treated by operation, but nevertheless an excellent functional result may follow with wide separation of the fragments. I have an intimate friend who fractured his patella about 30 years ago. He has wide separation of the fragments, but walks without a limp and without inconvenience, and takes strenuous exercise. (3) Operation followed by bony union is not always followed by a good functional result. (4) If the fracture occurs near the ligamentum patellæ, the knee-joint may not be opened, as the synovial membrane is reflected from the posterior surface of the patella some distance from the inferior tip of the bone. (5) Circumstances will arise when a fractured patella cannot be sutured under favourable conditions, and if the conditions are not ideal the attempt should not be made.

The first part of conservative treatment is to get rid of the effusion. To accomplish this, the limb should be elevated to relax the quadriceps extensor muscle and a tight bandage applied over several layers of wool. A practical way of helping absorption is suggested by Scudder:

Two slightly moistened bath or carriage sponges are allowed to dry under pressure sufficient to flatten them. These are placed upon each side of the knee and over it, and are held by a few turns of a roller bandage. Cold water is then poured over the whole. As the sponges absorb the water they enlarge, causing equable and firm pressure on the knee, thus very materially hindering the accumulation of fluid and favouring its absorption. *This dressing is repeated* every day. When the effusion has disappeared a calliper splint can be applied, in the manner recommended by Jones. The calliper splint should be worn for about two months. Full flexion of the knee should then be restrained for a time by a knee-cage, to prevent gradual separation of the fragments.

There are many other methods employed, the "Middlesex Hospital" method being one of the best.

Fig. 1.



Fracture of the patella treated by horse-shoe strapping and back splint. (Cheyne and Burghard.)

Fig. 1 shows the upper fragment pulled down by a horse-shoe shaped strapping to the foot-piece of a back splint.

Operative Treatment.

In dealing with fractures of the patella by operation we must be certain that the largest synovial cavity in the body is not exposed to the slightest risk of accidental infection. If a disaster occurs the knee will be partially or completely stiff. If partially, the joint will be painful. Amputation of the thigh may become necessary in severe sepsis.

I have never performed any complicated operation, such as plating or bone grafting, for fractured patella. A simple procedure is adopted:

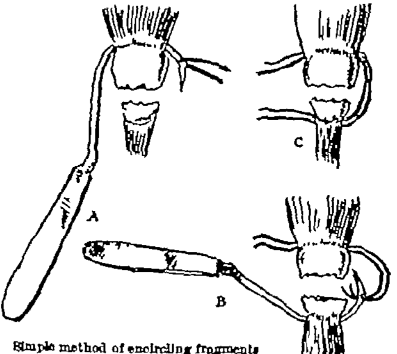
The joint is opened between the two fragments by a curved or transverse incision. Clots and torn tissues are cleared away from between the fragments. Doyen's or Reverdin's needle is passed through the quadriceps tendon in close contact to the upper margin of the patella. The needle is threaded with a fine loop of aluminium bronze wire and pulled through. The loop is cut and the needle is passed through the ligamentum patellæ in close contact to the lower border of the lower fragment; the double wire is again threaded and pulled through. The ends of the wire are now twisted and tied tightly, bringing the two fragments into apposition by an encircling suture. The torn portions of the capsule and aponeurosis are stitched with a few points of catgut. The wound is dressed. No splint is applied, and the patient is allowed to practise voluntary movements from the beginning, so far as he is able to do so without pain. (Fig. 2, A, B, and C.)

---

* Lectures I., II., and III. appeared in The Lancet of August 15th and 22nd and Sept. 5th respectively.

I have found that these cases walk about with the help of a stick after a fortnight or three weeks, and that they return in two or three months with bony union and full movement of the joint.

FIG 2.



Simple method of encircling fragments with wire.

FRACTURES OF THE TIBIA.

Fractures of one or both condyles of the tibia occur either as the result of distortion or from direct violence, just as in the case of fractures of the condyles of the femur. They may or may not involve the joint, and the treatment is identical with that already outlined for fractures of the femoral condyle.

Fractures of the spine of the tibia, associated with rupture of the crucial ligaments, are not very uncommon. Jones mentions 25 cases. I have seen them from time to time at Mercer's Hospital as the result of severe violence. In one case the tibia was completely dislocated backwards. The knee-joint is immobilised in plaster of Paris, and neither active nor passive movements allowed until two months have elapsed. Then very gradual and gentle movements are allowed. A Thomas walking calliper may be substituted for plaster fixation. If, following this treatment, movements are restricted as a result of a bony block produced by a detached spine uniting by callus, the knee-joint must be exposed by longitudinal division of the patella, and the bony block removed.

OSGOOD'S OR SCHLATTER'S DISEASE.

The condition is sometimes spoken of as "Rugby knee." Pain and tenderness rapidly disappear under rest treatment, and a knee cage should be worn limiting flexion of the knee and the activities of the patient for some months. The epiphyseal strain may exist without much difference between the X ray appearance of the normal and abnormal bone.

FRACTURES OF THE TIBIA AND FIBULA
(UPPER THIRD).

These injuries have received but scant attention, owing to the ease with which treatment can be carried out. The treatment is identical with that of fractures of the condyles of the femur, and consists in manipulating the fragments, while an assistant is fixing the extension tapes to the end of a Thomas splint. Loops of bandages are applied to control any lateral or antero-posterior deviations.

FRACTURES OF THE LOWER THIRD.

It is when we come to the common broken leg, that is to say, an oblique or spiral fracture of the lower end of the tibia, with a fracture of the fibula at a slightly higher level, that real difficulties in conservative treatment arise. Fractures of the tibia alone, or of the fibula alone, are already splinted by the uninjured bone. A little extension and manipulation will easily correct any slight displacement, and the limb can be encased in plaster of Paris from the foot to above the knee. At the end of six weeks, weight may be borne on a walking calliper.

Fracture of the fibula alone, without displacement of the foot, is only of interest because the diagnosis may be missed. Special attention should be paid to the ecchymosis which appears some time after the injury, and often extends up along the line of the fibula. The same ecchymosis arises in all fractures, including fractures of the base of the skull. In doubtful cases of fracture of the long bones without displacement, ecchymosis following the line of a bone should put the practitioner on guard. If extensive ecchymosis coexists with a point of maximum tenderness, a fracture is almost certainly present.

These remarks apply to fractures of the fibula, both in its upper and lower thirds.

Walking may be allowed when it is possible to do so without causing pain. No form of splintage is necessary. When the fracture is near the ankle-joint it is wise to wear an outside iron, or to raise the inner side of the boot, so as to anticipate any possibility of valgus deformity occurring under the strain of weight-bearing.

Treatment of Fractures of the Lower Third of the Tibia and Fibula.

With the oblique and spiral fracture I have had more difficulty and seen more bad results than in any other fracture of the lower limb. Anyone with experience in setting these fractures knows that manual extension of the foot is very unsatisfactory. If it is a recent case, and it is decided to fix the limb in plaster from the foot to well above the knee, the hands of the assistant get in the way at every turn of the lower part of the bandage, and displacements occur. It is impossible for an assistant to keep up sufficient extension and to keep the fragments in alignment during the application and setting of the plaster in a difficult case. On the other hand, there is not sufficient of the limb below the fracture to apply adhesive strapping for fixation to the end of a Thomas splint.

Sinclair's foot-piece and glue, as a means of putting extension on the lower fragments, has given satisfaction to many surgeons, but, after failures by this and other methods, I have adopted the following plans sometimes singly and sometimes in combination.

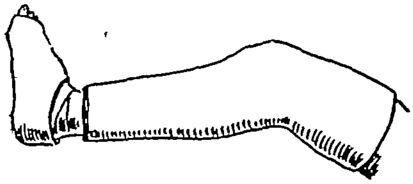
1. In certain cases, with the patient under an anæsthetic, and the knee held flexed by an assistant, extension and manipulation of the foot readily reduces the shortening, and corrects the alignment. If steadily held, there is no great tendency to recurrent displacement of the fragments, and the assistant experiences little difficulty while the limb is immobilised in plaster.

2. The deformity can only be reduced with difficulty, and the slightest move of the foot brings about slipping of the fragments. In such cases the sectional plaster of Paris method, as recommended by Cockerill, is useful. (Fig. 3.) I have a case so treated at present in Mercer's Hospital. By the sectional plaster method is meant that separate plaster casings are applied and allowed to set above and below the injury. The injured area remains exposed and free for manipulation. The first section of plaster should be applied from just above the fracture to the middle of the thigh, with the knee slightly flexed. The second plaster encases the foot. The two sections are allowed to set, and the plaster is trimmed at the edges. The foot is now fully dorsiflexed in slight inversion by the assistant, while the surgeon unites the two plasters by a few turns of a third plaster bandage. If more extension is required than can be obtained comfortably by manual traction, a clove hitch is placed round the foot encased in its plaster and attached

to the gates (see Lectures I. and II.), or pulled upon by means of a block and tackle arrangement. The two plasters are then united as before.

3. When more than manual traction is necessary, the clove hitch over the plastered foot is a somewhat clumsy, though effectual, method of reduction. It is better, I think, to pass a long nail under the tendo Achillis in contact with the os calcis, and connect this through the medium of a wire hoop to the end of the gates, so that forcible extension may be applied. The surgeon simultaneously manipulates the fragments into position, and takes care to pull the heel well forward. There is now no difficulty whatever in applying plaster of Paris, and the extension is not released until the plaster is set. The pin and wire stoop are partially encased in the plaster, but can easily be removed.

Fig. 3.



Sectional plaster of Paris in the treatment of fractures of the lower third of the leg.

4. It will become obvious in certain cases that nothing but continuous traction will reduce the overlapping and shortening. In such cases the nail is passed *through* the os calcis, and after forcible extension on the gates, the hoop of wire is fixed tightly to the end of a Thomas splint until the patient is back in bed. This fixed extension may be continued, but in these cases heavy weight-and-pulley extension is better through the medium of the nail—the Thomas splint merely acting as a sling. It is best to pass the nail obliquely through the os calcis on a slightly higher level on the outer side, so that as traction is employed the tendency is slightly to invert the foot. (Fig. 4.)

5. Operation with internal fixation should be the last resort. Probably the best way of securing the fragments is by means of Parham's bands.

Quite often after open reduction no fixation will be found necessary, and the treatment can be continued by any of the methods mentioned above.

Pott's Fracture.

The original description of Pott's fracture, as given in 1768, has been quoted recently by Sir D'Arcy Power, and is well worth reading. To this day Pott's fracture, in the wards of the big hospitals, constitutes a favourite subject for discourse to students, yet the treatment and the results are far from being universally satisfactory. It is the old story: Want of proper reduction at the time of the injury and want of precautionary measures to prevent displacement when weight-bearing is permitted.

The fracture is produced by violent eversion. The astragalus is thrown against the external malleolus. The ligaments binding the fibula to the tibia remain intact and act as a fulcrum, and the shaft of the fibula breaks at the weakest point near the ankle. The importance of the fracture lies in the fact that the astragalus is displaced outwards, perhaps half-way across the articular surfaces of the tibia as well as backwards. The thrust of the foot, if the deformity is not corrected, is between the tibia and the fibula, and not squarely on the tibia. The backward displacement prevents dorsiflexion of the foot, by the contact of the neck of the astragalus with the anterior edge of the tibia.

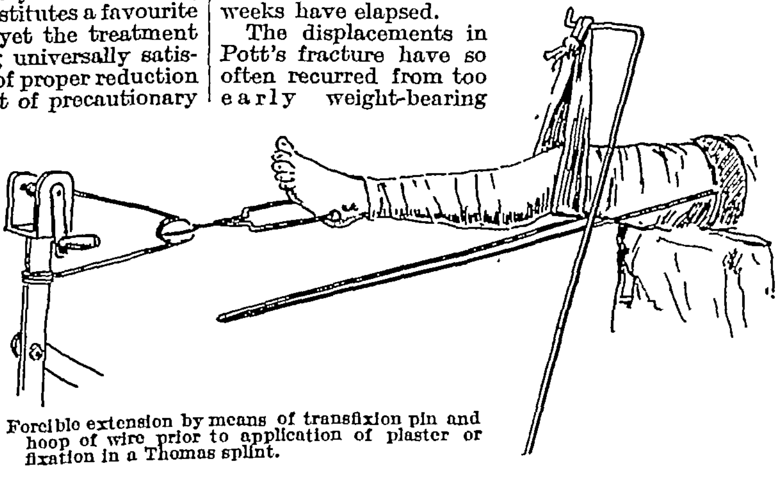
A patient with an improperly reduced Pott's fracture can never walk without pain in the ankle and pain on the inner side of the knee with a tendency to knock-knee. The distortion outwards of the foot leads to a condition of flat-foot, a further addition to the misery of the patient. If there is much displacement outwards of the foot, the internal malleolus or the internal lateral ligament must, of necessity, be torn. Pott's fracture may be transformed into a Dupuytren's fracture by forcing the astragalus up between the tibia and the fibula. The astragalus may carry with it a portion of the articular surface of the tibia; a piece may be knocked off the anterior portion of the tibia and block dorsiflexion, or a portion of the back of the tibia may accompany the backward dislocation of the foot. (Figs. 5 and 6.)

Whatever the complications the treatment is the same. Under an anæsthetic the outward and backward displacements must be reduced. As in fractures of the lower third of the tibia and fibula, relaxation of the tendo Achillis by flexing the knee is an advisable preliminary. The foot is then forcibly twisted inwards in order to bring the astragalus squarely under the articular surface of the tibia, and at the same time the heel is pulled steadily forward until the foot can be dorsiflexed with ease beyond a right angle. The foot must be maintained in this position of dorsiflexion and exaggerated inversion.

The displacement does not readily recur after reduction, and any form of splint intelligently applied will secure fixation. A board or gutter splint secured to the outer side of the leg and well padded at the lower extremity will, by a thrust, keep the foot inwards. Dupuytren's splint and Symě's splint are still employed. Plaster of Paris in a recent case is an admirable means of fixation. It should extend—as in fractures of the lower third of the leg—from the foot to above the knee. It is best to make two plaster splints composed of several folds of superimposed bandage. One strip is made into a posterior splint, which extends from the toes along the sole, round the back of the heel, and up beyond the knee-joint behind. The other strip is moulded in position while the foot is held in inversion, and extends from the external malleolus over the dorsum of the foot to the inner side under the sole, and upwards along the outer side of the leg to the same height as the posterior splint. The posterior splint is applied first, and both are secured in position by a roller plaster bandage. The foot must be held in the correct position during the setting of the plaster of Paris. They can be easily removed in about three weeks for massage and movements, but should be reapplied in the intervals until another three weeks have elapsed.

The displacements in Pott's fracture have so often recurred from too early weight-bearing that it is best to prohibit walking for at least two months from the original injury, and before walking is allowed the inner side of the heel and sole of the boot should be raised so as to maintain a slight varus position.

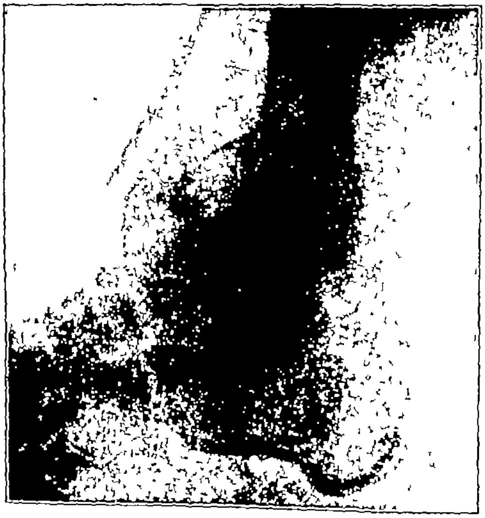
Fig. 4.



Forcible extension by means of transfixion pin and hoop of wire prior to application of plaster or fixation in a Thomas splint.

In dealing with patients who are not helpful, or in heavy subjects, it is wise to prescribe an outside iron and an inside cross strap, so as to ensure support and inversion. I will describe three cases, but I have had many, in which the patient was treated accurately while in hospital, but when weight-bearing was resumed the callus was not strong enough to bear the strain, and the patient returned with pain and disability consequent on gradual yielding in the direction of the original displacement. It is important to know what to do in cases which have been allowed to walk four or five weeks *after the accident* without support and who come back suffering from pain and a valgus deformity.

FIG. 5.



Fracture of fibula with portion of tibia detached and blocking *dorsiflexion.*

CASE 1.—The patient was a big, heavy woman, who refused to stay in hospital more than a week. The displacements were reduced, and the foot put in plaster of Paris. She commenced weight-bearing at the end of a month, and then returned to the extern department of the hospital, with pain and some slight eversion and tenderness at the site of fracture An X ray photograph showed no displacement. The boot was raised on the inner side, and an outside iron fitted so that the foot was well inverted. In this case, a recurrence of the deformity was anticipated and prevented.

CASE 2, a private patient, came for advice seven weeks after her accident. The fracture was reduced correctly by her local doctors, but she began to walk without permission and without support after the lapse of a month. An X ray photograph showed the astragalus displaced outwards and somewhat backwards. The patient was anæsthetised, and thorough wrenching in an inward and forward direction was carried out with a Thomas wrench. This procedure did not appear to bring the foot satisfactorily into position, and an osteotomy of the fibula was done. Further wrenching after the osteotomy *completely* corrected the displacement. Three weeks later she *was discharged* in a light plaster case, and shortly afterwards was fitted with an outside iron and a crooked heel. Her progress was quite satisfactory.

CASE 3.—This patient came back a year after recurrence of the displacement. The fibula was divided, and a cuneiform osteotomy performed on the inner side of the tibia, after the method of Jones, so that inversion of the foot could be obtained and the weight thrown on the outer side of the foot without making any attempt to reconstruct the joint.

This simple form of osteotomy has given me good results. I have never undertaken the reconstruction of the fracture, as recommended by Murphy and others.

The patient is seldom quite well and free from pain after a Pott's fracture in less than six months. It may sometimes be necessary to do an open operation, when a portion of the tibia, either in front or behind, is torn off and mechanically blocks the movements of the ankle-joint, but in cases seen early forcible manipulation will usually secure a right-of-way in every direction.

FRACTURE OF THE ASTRAGALUS.

Sometimes from heavy falls on the foot the astragalus may break instead of the tibia and fibula. There is often an irregular comminution of the body, or the neck may be fractured, and to all intents and purposes the latter fracture is outside the ankle joint. Forward dislocation of a fractured astragalus can be reduced by traction on the foot, and, if necessary, the tendo Achillis is divided in order to pull the os calcis away from the tibia. In some cases the fractured bone gets so twisted and displaced that astragalectomy becomes necessary. In cases of fracture of the neck, as distinct from fractures of the body, there is usually little displacement, and treatment should consist in placing the foot in full dorsiflexion in plaster of Paris for three weeks. Weight-bearing should not be allowed for two months.

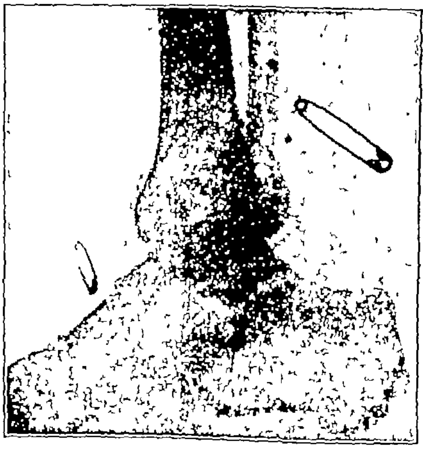
Sometimes a little *ossicle of bone,* described by Pirie, is seen between the astragalus and scaphoid as if detached by an injury; a comparison with the sound side will sometimes show a similar condition. The recognition of "Pirie's ossicle" is of medico-legal importance; it is not the result of injury.

Thurstan Holland, in the *Journal of Anatomy,* July, 1921, deals with the significance of this ossicle.

FRACTURE OF THE OS CALCIS.

The bone may be torn by muscular action at the point of insertion of the tendo Achillis. It may be crushed, fractured transversely or longitudinally, and may be associated with fracture of the astragalus. Complete plantar flexion of the foot may be needed to bring the fragments well into position and to take the pull of the tendo Achillis

FIG. 6.



Fracture reduced and treated in plaster of Paris.

from the posterior fragment. A traumatic flat-foot often results from unreduced fracture of the os calcis or astragalus.

The treatment in the first instance should anticipate this possibility, and after attempted reduction the foot should be placed in slight inversion.

Fractures of the os calcis give unsatisfactory results, a painful heel often persisting whatever treatment is adopted. The treatment of this unsatisfactory late result was discussed by Cotton in "Annals of Surgery," 1921. He regarded it as being due chiefly to excessive new bone formation on the outer side locking the fibula to the os calcis, and he recommended a U-shaped incision under the external malleolus, the turning up of a subperiosteal flap, and a wide removal of bone in this area.

Fractures of the Scaphoid.

Bennett described two examples of fractures of the scaphoid bone of the foot in 1884. The articular surface which receives the head of the astragalus presented lines of ununited fracture, but on the opposite surface—in contact with the cuneiform bone—the lines of fracture were quite indistinct.

Thurstan Holland draws attention to the presence of a distinct skeletal bone situated at the posterior external side of the tuberosity of the scaphoid which has been mistaken, after injury, for a fracture of the tuberosity of the scaphoid. To assist in the diagnosis, the other foot should always be examined. The bone is usually known as the "tibiale externum."

Fracture of the Metatarsal Bones.

Fracture of the metatarsal bones usually causes flattening of the transverse metatarsal arch. Treatment is directed to restoring this and maintaining fixation for some weeks. A pad should be applied in the cavity of the arch, and the latter kept in position by a circle of adhesive strapping. To prevent metatarsalgia, weight can be prevented from falling on the fractured bone by a transverse metatarsal bar across the sole of the boot. It must be remembered that a small portion of the base of the fifth metatarsal bone may be detached normally and remain as a separate bone throughout life—"the bone of Vesalius"; it appears in an X ray photograph as if a fracture.

Fracture of the Sesamoid Bones.

The sesamoid bones must not be forgotten. Cases have been reported by Hall Edwards, by Scales, and by Muller, which were operated upon and the diagnosis of fracture confirmed. Kellog Speed lays great stress on these injuries, and says they are usually due to a heavy object falling on the foot, or sudden increase in weight-bearing force when carrying heavy objects.

Physical examination reveals little, but by finding persistent tenderness under the head of the first metatarsal, the possibility of this fracture should be considered. Out of five cases, four were found to be fractures of the internal sesamoid, which is more distinctly in relation to the head of the metatarsal bone. The best treatment is removal by operation.

Thurstan Holland states that, developmentally, the inner sesamoid may be in two, three, or even four separate bony pieces. Many times, says Holland, such a bone has been described as fractured when there has been a history of injury, but, in his experience, fracture must be a very rare occurrence, and most of the so-called fractures are really nothing of the kind. Comparison should be made with the other foot. In the same paper, he reminds the surgeon of the bone of Vesalius, referred to above, which is probably a persistent epiphysis, part of the spur-like process at the base of the fifth metatarsal bone. At first sight it looks like a chip of bone separated as a result of injury.

Operative Treatment of Fractures.

In these lectures I have confined my remarks to the conservative treatment of fractures, but operation may be part of the conservative treatment, and in a number of cases, especially when necessary appliances are not available, the displacement of fractured extremities may be reduced without internal fixation by open operation. Afterwards the treatment along conservative lines is continued.

In very few cases within recent years have I found it necessary to apply plates, screws, metal bands, or bone grafts.

I think the internal fixation of fragments with foreign bodies served a useful purpose during a period when splints, such as Liston's splint, Cline's splint, and MacIntyre's splint were the best known to surgery, and were often responsible for deplorable results. During this period neither traction nor suspension was generally understood. I think plates and screws have done the same service in the surgery of fractures as Murphy's button has done in the case of intestinal surgery, at a time when the technique of suture of the intestines was in its infancy. The work of Sir Arbuthnot Lane, and others of the same school, has been an immense impetus to those working for better results in the treatment of fractures, and I believe it will go down to history as an important landmark in the march of surgery.

It appears to me that the time has arrived when the routine operative treatment of recent fractures must be regarded as a confession of failure—a confession that the surgeon is unable, by manipulative methods, to reduce deformity and to keep deformity reduced until a first-rate functional result is assured. Imagination and skill are more often required in the non-operative than in the operative method of treatment. The management of a case for the first three or four weeks requires constant and minute attention, but these disadvantages must be offset against the very real dangers in connexion with operation, especially in the case of fracture of the femur. Even assuming the most perfect surgical technique, delayed union, non-union, delayed infection, perhaps through the blood stream, may take place, and the treatment of fractures so complicated must be commenced de novo under the most unsatisfactory conditions. I speak only of recent fractures. If conservative treatment is not successful in the first instance, a new beginning can usually be made with a bright outlook, provided too long an interval of time is not wasted before the surgeon sees the error of his ways.

The wave of thought in favour of operative treatment of fractures during the decade prior to the war was due to faulty teaching in orthopædic methods. Every student was taught with minute accuracy how to reduce dislocations. No surgeon ever dreamt, unless under very exceptional circumstances, of reducing dislocations by open operation. It was different in the case of fractures. I can remember quite well how minutely I was taught the mechanism of the displacement of the fragments in the case of fractures, and when that aspect of the injury was completed, the teachers and the text-books went straight on to a detailed description of a multitudinous variety of splints and the methods of their application. There was hardly an intelligent sentence in reference to the all-important subject of reduction.

It is on reduction of displacements and the attainment of a perfect alignment that union and a good functional result depend. I can give no better example of this than fracture of the neck of the femur. It was no wonder that a rising generation of surgeons before the war determined that by some means or another alignment and reduction must be assured, and in an aseptic era the easiest method appeared to be open operation.

The war has come and gone, and we know that by non-operative methods we should be able in the great majority of cases to attain perfect alignment and a perfect functional result free of risk, immediate and remote. To this day there are cases, few and far between, where a Murphy's button is of use in intestinal surgery, and so occasionally operation will be needed in a surgeon's practice. In the realm of fractures there still remain the patella, the olecranon, and a rapidly decreasing number of the oblique fractures of the lower third of the tibia and fibula, which may defeat all efforts at conservative treatment.

ON THE EXPERIMENTAL TREATMENT OF IMPLANTED MALIGNANT TUMOURS OF THE RAT.

BY THOMAS LUMSDEN, M.D. ABERD.

(*From the Department of Experimental Pathology, Lister Institute.*)

IN a previous communication[1] the effects of an antiserum upon cancer cells, growing in vitro, were detailed. It was shown that if 1–2 g. of finely divided mouse carcinoma (M. 63, Imperial Cancer Research Laboratory) were injected into the peritoneal cavity of a rat or rabbit weekly for two to three months, a concentration of antibodies, sufficient to kill cancer cells in vitro within a few minutes, was obtainable in the serum of the rat or rabbit. If mouse heart muscle, spleen, kidney, or salivary gland were grown on the same slide as a fragment of mouse cancer, an application of the antiserum, which killed the cancer cells rapidly, did not seriously damage the normal mouse tissues. Thus a fragment of heart muscle might beat and grow in the antiserum for four or five days, after the death of the cancer cells cultured alongside of it. Since the above facts were published they have been confirmed more than 200 times, and no single instance has been observed in which cancer or sarcoma cells could survive in an antiserum made as above directed.

The object of the experiments now reported was to determine whether comparable results could be obtained in the living cancerous or sarcomatous animal.

Experimental.

The tumours employed were the mouse carcinoma (M. 63 of the Imperial Cancer Research Laboratory) and Jensen's rat sarcoma. In most cases the sarcoma was used because it was found that while M. 63 is very satisfactory for in vitro work, it is less suitable for experiments in vivo. It is a hæmorrhagic tumour and tends to degenerate readily, so that when it attains a considerable size it consists of an actively growing shell surrounding a central mass of degenerate tissue. Its hæmorrhagic nature made it almost impossible to obtain an antiserum which did not contain a large amount of agglutinins and lysins for mouse red blood corpuscles, which naturally increased its toxicity. These could be absorbed, but the serum obtained from one rabbit might require the corpuscles of several dozen mice for its complete absorption. Jensen's rat sarcoma, on the other hand, grows freely and, even when it attains large proportions, consists of a mass of healthy malignant cells with a minimum of stroma and free from hæmorrhages. Central degeneration sets in very late, and although this tumour, like all others, may occasionally absorb before it gets a firm footing, it practically never does so when well established, say, in the flank of a healthy young rat. Thus, with the precautions taken in the following experiments, out of considerably over 100 tumours of the foot only two absorbed spontaneously, and of over 400 established tumours of the flank or back in young rats I have not seen one example of unaided recovery.

A. *Infectivity of Cancer Cells Previously Treated with Antiserum.*

In order to determine whether cancer cells treated with antiserum in vitro were capable of producing a progressive tumour in vivo the following experiment was undertaken. Mouse carcinomata were removed aseptically and the healthy portions finely divided up with scissors. Of this material about 1 g. was transferred to a heavy watch glass and 5 c.cm. of normal rabbit serum was added. To a similar amount of the tumour tissue in another watch glass 5 c.cm. of antiserum was applied. The watch glasses were covered with glass plates, and sealed with vaseline to prevent evaporation. They were then placed in an incubator at 37° C. for periods varying from three to six days. In other instances the fragments of cancer to be used for inoculation were cultured separately by the ordinary hollow slide and cover-glass method, in normal rabbit serum, or in antiserum from an immunised rabbit. The results of these two methods were exactly similar and may be given together.

Of 15 mice inoculated with cancer cells cultured in normal serum for from three to seven days, seven developed progressive tumours—i.e., 46·6 per cent. Of 20 mice inoculated with cancer cells kept for three to six days in antiserum not one developed a progressive growth; in all cases, however, an inflammatory reaction was seen at the site of injection which passed off in seven to ten days. It appeared then that the antiserum had so damaged the cancer cells that they were unable to infect when inoculated into normal mice or else the immunity induced by the absorption of the attenuated cells was sufficient to prevent tumour formation.

B. *Investigations of the Curative Effects of Antiserum in Vivo.*

The antisera are definitely toxic and irritant; thus it was found that 0·25 c.cm. of unabsorbed M. 63 antiserum when injected into the tail vein might kill a 25 g. mouse within 10 to 30 minutes. If the antiserum were fully absorbed with mouse red blood corpuscles then 0·4 or 0·5 c.cm. might sometimes be safely given. When a fatal dose is injected, intense dyspnœa and collapse come on within five minutes, and post-mortem examination invariably shows the presence of acute œdema and congestion of the lungs. Similar results were obtained with Jensen's sarcoma antisera.

Experiments with Jensen's Rat Sarcoma.—The antisera produced as described were obtained from rabbits which had been inoculated weekly from 8 to 16 times with from 1–2 g. of minced Jensen's rat sarcoma. In all cases the sera were tested on healthy growing cultures of Jensen's rat sarcoma in vitro, and invariably cytolysis was observed. It was, however, only after prolonged inoculation that the rabbits gave a highly specific serum. The antisera were tested in sarcomatous rats in the following ways.

1. By injection into the tail vein. As in cancerous mice no curative effect was consistently noticed.

2. Subcutaneously at a point remote from the tumour. This was without benefit. In 1908 Walker[2] reported that in a batch of ten mice treated with subcutaneous injections of an antiserum, the tumours in seven dried up and came away as small scabs. He does not state whether recurrence took place. With the tumours I have employed and using a slightly different technique, I have never obtained satisfactory results.

3. By injection into a tumour of the flank. When the growth was small some amelioration resulted. Out of six rats so treated only one completely recovered. In the case of large tumours gangrene or sloughing may follow such inoculations, but recurrence almost invariably takes place in the ulcerated area so produced.

These unpropitious results were so unlike the invariably lethal effects obtained on the tumour cells in vitro that it was suspected that the antiserum could not have come into intimate contact with the cells in adequate concentration for a sufficient period. An attempt was therefore made (it would be easy in man or any other large animal) to inject the antiserum into the artery going to the affected area and to close the corresponding veins. Even in a large rat this was found to be impracticable on account of the small size of the blood-vessels.

For this reason in the last 100 experiments the following technique was adopted. Rats were inoculated with Jensen's rat sarcoma in either the right foot alone or in both feet, and after two to three weeks when the tumours were well established and had attained the size of a green pea (Fig. 1, A) the antiserum was injected into and around the tumour. In most cases before the injection a rubber band was applied round the ankle and the constriction was so graded as to just completely shut off the blood circulation. The purpose of the constriction was to maintain around the tumour a high concentration of the antiserum for an appropriate period. It was found that by means of this manœuvre definitely curative results could always be obtained.

---

[1] THE LANCET, Feb 21st, 1925.

[2] THE LANCET, Sept. 12th, 1908.

After many trials of different doses of antiserum and varying degrees and duration of constriction, the most effective procedure was found to be as follows. Immediately after applying the rubber band 0·2 c.cm. of antiserum was injected into the tumour, after 15 minutes a further dose was given, and an hour later a third and final injection of 0·2 c.cm. was made. The rubber band was removed after two to three hours from the time of its application. When this was done and repeated in a day or two if the tumour still looked active, in the great majority of cases the tumour disappeared though sometimes, when the growth was large, some loss of normal tissue also occurred. After removal of the constricting band the foot rapidly swelled, and not infrequently some hæmorrhage into the tumour took place. Within three to four days the growth became inactive, either gradually absorbing or forming a brown or blackish crust which separated after 10–14 days, leaving a small healthy scar (Fig. 1, B and C). No instance of recurrence after complete healing has been seen.

In four animals cure was effected without constricting the limb. In this case a preliminary inoculation caused—as it invariably does—inflammatory œdema within five to ten minutes. Into this œdematous area a second and later a third inoculation was made 15 and 60 minutes after the first. In six other animals so treated the tumour continued to grow, and cure was only effected after antiserum with constriction.

The actual results in the last 50 animals treated and the controls employed were as follows:—

Animals treated 50

J.R.S., of foot 46; of tail 4.

Animals cured 41

Without serious loss of normal tissue, 35 (foot 33, tail 2); with loss of foot 4, of tail 2.

Animals not cured 9

Tumours of right foot very large, 2; ulcerated, 2; without constriction, 2. Coexisting large tumour of back, 3.

Control animals (8 recovered) 50

Tumour of foot—spontaneously, 1; of tail after constriction + nor. ser., 3; of foot after constriction + nor. ser., 2; of foot after constriction + AgNo$_3$ (5 per cent.), 1; of foot after constriction antiplatelet serum, 1.

Other controls (none of which recovered) .. 42

Constriction and nor. ser., 11; constriction alone, 10; antiplatelet serum and constriction, 2; iodine 0·3 per cent. + constriction, 2; untreated, 16; constriction and AgNo$_3$ (5 per cent.), 1.

It will be seen that of animals treated 82 per cent. were cured; the 18 per cent. uncured included large or ulcerating tumours in which the *antiserum* escaped when injected Of the controls 2 per cent. recovered spontaneously, a further 14 per cent. recovered after control treatment of various sorts, 84 per cent. produced progressive tumours. It was noticed that antisera in which the hæmolysins and agglutinins had been absorbed, though only about half as toxic, were rather more effective against the sarcoma than the unabsorbed antisera.

It must be appreciated that convincing results are only to be attained after very considerable experience and with careful attention to certain essential details. It may be of value here to specify the precautions which are necessary to that end.

1. A potent and specific antiserum must be obtained. This should be tested upon cultures of Jensen's rat sarcoma in vitro before use.

2. The investigator must acquire experience sufficient to enable him to grade the constriction so as not to cause destruction of the foot, and to apply, and if necessary re-apply, the serum in appropriate dose.

3. The antiserum must be sterile, for septicity invalidates the results. If a large septic ulcerating area exists, discharge escapes, and there may not be sufficient absorption from the dying cells to evoke immunity.

4. Only healthy young rats (six weeks to six months) and a vigorous strain of tumour must be used, otherwise the controls might not grow with certainty. In any single experiment the animals should be as far as possible similar in age, breed, &c.

5. Treatment should be begun only when all the tumours are well established and about the size of a green pea.

6. The controls should, as a rule, be equal in number to the cases treated.

C. *Immunity after Cure by Antiserum.*

Bashford, Murray, Haaland,[3] and others have shown that if an animal spontaneously recovers from any particular inoculated tumour it is in future immune thereto. In order to discover whether a similar immunity followed the disappearance of growths after treatment by antiserum + constriction, all the animals which had recovered from sarcoma of the right foot and those which had not been cured were from four to nine weeks after the original implantation inoculated with a fresh graft of Jensén's rat sarcoma in the left foot. All were injected on the same day and with the same tumour material and dose. In all cases a tumour appeared and increased in size for seven to ten days, but thereafter, in those animals in which antiserum treatment had cured a tumour of the right foot, the tumour of the left foot rapidly disappeared. In the animals in which treatment had failed or had resulted in serious loss of tissue, the tumours implanted in the left foot increased and formed typical progressive sarcomata (Figs. 2 and 3). When examined 14 and 21 days after the test implantation of Jensen's rat sarcoma into the left foot, the following were the results. In 35 animals in which the original tumour was cured without serious loss of tissue, 35 were apparently immune—i.e., no tumour developed on the left foot. In six animals with loss of the foot or tail as the result of treatment of the original sarcoma, six proved to be not immune—i.e., a progressive tumour developed on the left foot (Fig. 2). In nine animals in which treatment of the right foot tumour was unsuccessful eight were not immune—i.e., tumour developed on the left foot; one was apparently immune—i.e., the implant in the left foot did not develop.

It will thus be seen that after cure of the tumour of the right foot or tail, by means of antiserum and constriction, the proportion of animals showing general immunity, as evidenced by failure of inoculations of Jensen's rat sarcoma into the left foot, and later into the right axilla, reaches 100 per cent. While if absorption of products from the original tumour was prevented by separation of the extremity no immunity resulted (Fig. 2).

D. *The Effect Produced on a Jensen's Rat Sarcoma Tumour of One Foot, by Treating with Antiserum a Similar Growth of the Other Foot, both Tumours having been Implanted at the Same Time.*

From a number of rats inoculated with Jensen's rat sarcoma in both feet at the same time, 14 in which the tumours had become well established were selected. Of these, five which bore the smaller tumours were retained as controls. In the other nine rats, the tumours on the right foot only, were treated by antiserum + constriction. The experiment was somewhat interfered with by an epidemic of enteritis, but the following results were obtained:—

Tumours of right foot, treated, 9; cured, 9. Controls untreated, 5. Progressive growth, 5.

Tumours of left foot in surviving treated rats, 7; disappeared, 5. (Fig. 4.) In control rats, 5; progressive growth, 5. (Fig. 5.)

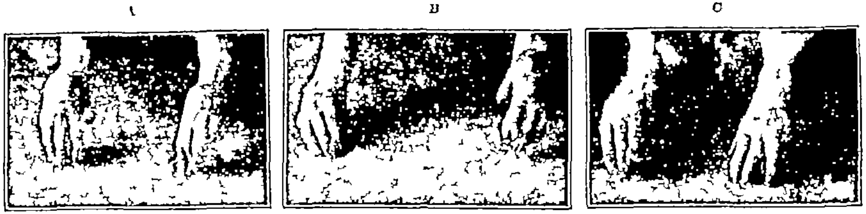
FIG 4

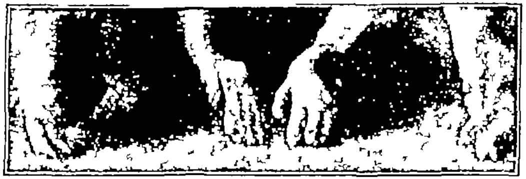


A. R. L. Tumour of both feet before treatment.

B. R. L. Right foot tumour removed by antiserum. Left tumour inactive though untreated

C. R. L. Both feet now free from tumours. Only right foot was treated.

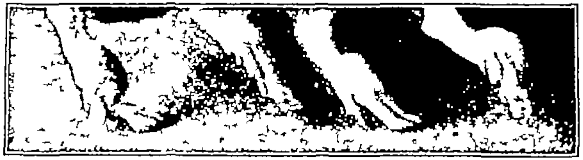
FIG 3



R. L. R. L.

Right and left feet of two rats. The tumours on the left feet show absence of immunity when original (right) tumour not cured.

FIG 5



R. L R. L.

Two control rats with tumours of both feet untreated and growing progressively.

Two of the treated rats died of enteritis after cure of the right foot though before the left foot tumours, which had begun to absorb, had time to disappear. But even discounting these, the results show: Of seven surviving treated rats, in all the right (treated) foot is cured, in five the left (untreated) foot is also cured (Fig. 4). Of the two remaining left foot tumours, one is retrogressing and will almost certainly disappear, one still looks active. All the ten tumours in the control rats grew progressively (Fig. 5).

Discussion.

From observation of the action of antiserum on cancer fragments in vitro the following facts emerge.

1. Malignant cells which have migrated out from the fragment are killed, in a few minutes they cease to move, and the fine fatty granules become irregular in shape and clump together. The nucleus shrinks leaving a transparent ring around it, and the same is true of the granular cell cytoplasm. Later cytolysis occurs and the bodies of the cells become invisible unless stained and are represented only by an irregular mass of protoplasmic debris surrounded by a few large fatty globules.

2. The antibodies diffuse very slowly into the solid fragment of cancer, so that living cells can still be seen in the centre of the fragment even one or two days after antiserum has been applied to it.

If the culture is now fed with normal serum a few cells may again migrate out into the medium. A second application of antiserum may be required in order to kill the whole of the malignant tissue.

The poor diffusibility of the antiserum partly explains why it acts so inefficiently when injected without coincident constriction directly into a tumour in vivo. A further cause of failure is that without stoppage of the circulation in the tumour area, a high concentration of the antiserum cannot be attained locally. When injected into a sarcoma the antiserum forces a passage through the compact mass of malignant cells reaching lymph and blood spaces, from which it is absorbed very rapidly into the general circulation. This is shown by the fact that when a lethal dose of antiserum is injected into a tumour of the back death may ensue almost as rapidly (15–30 minutes) as when a fatal dose is run into the tail vein. The causes of failure when antiserum is injected into the peritoneum, the subcutaneous tissues, or intravenously are probably these: (*a*) The antiserum is diluted with the whole of the body fluids before reaching the tumour. (*b*) When the antibodies have entered the blood-vessels there is some difficulty in their leaving these again. (*c*) The inoculated animals appear to have some means of resisting or neutralising the foreign antibodies, for it is found that they tolerate without ill-effects a larger dose the second time they are inoculated. (*d*) There is some evidence that the antibodies are absorbed by a large new growth when present. Thus it was found more difficult to cure a tumour of the foot when there was in the same animal a large sarcoma of the back.

It is probably because most of the above points were overlooked that the many antisera heretofore used for the treatment of cancer in this country, and especially abroad, have invariably given disappointing results. I suggest that antisera to be directly effective in man ought to be injected into the arteries supplying the tumour area, and the corresponding veins and lymphatics should be tied or compressed.

The reason why sarcomata treated by constriction and injections of antiserum disappear, raises some points for discussion, but clearly the most important thing is the fact that these tumours can thus be got rid of practically at will, and that thereafter the rats dealt with are immune to the tumour concerned.

The possible factors causing the disappearance are: (1) Temporary stoppage of circulation. (2) Consequent retention of a high concentration in the tumour and its vicinity of antiserum injected thereinto, (*a*) acting as a non-specific irritant, (*b*) acting specifically on the sarcoma cells.

The controls make it abundantly evident that constriction as such alone plays, at most, a subsidiary part, for of ten animals so treated not one recovered. It is not so clear that constriction plus some non-specific irritant or some mechanical destruction of the tumour cells is equally ineffective. For of three rats treated with an anti-rat platelet serum kindly given me by Dr. S. P. Bedson, all showed very severe hæmorrhages into and around the tumours. One recovered and proved immune, two were not cured. When normal serum is inoculated several times into a tumour with coincident constriction recovery sometimes takes place; here it is possible that enough damage has been done mechanically to cause retrogression of the tumour. Two sarcomata of the foot and three of the tail disappeared after such treatment, while 11 continued to grow. In passing, it may be remarked that the tail is not a satisfactory site for experimental purposes since spontaneous absorption frequently happens in sarcomata in this situation.

On the whole, it seems probable that the specific cytolysins proved in vitro to be present in the antiserum are the main factor in the recoveries reported above. The fact that a fair proportion of cures follows the repeated injection of antiserum even without coincident constriction favours this view. The selective way in which the tumour was in most cases removed points in the same direction. In about 60 per cent. the growth retrogressed after antiserum and constriction, without apparent loss of any normal tissue; even the skin over the tumour survived, although in some cases tightly stretched and thinned out over a large growth. In most of the other cases of recovery a brown or blackish crust formed (Fig. 1, B) over the tumour area, and when this fell off 7 to 14 days later, a neat scar was left. In these cases just referred to no discharge escaped, so that all products of destruction from the tumour were absorbed into the general system. Such absorption is, I think, necessary if immunity is to supervene, and this explains why no immunity takes place when the tumour is removed surgically, when the limb becomes immediately gangrenous, or when a discharging septic wound or ulcer results from treatment.

The following seems to me to be the sequence of events: (1) When the antiserum is got into the lymph round the tumour cells and is maintained there for some hours in good concentration it selectively kills many of the malignant cells and damages others. (2) Absorption of the products of degeneration of these cells acts like a vaccine, and calls forth a general active immunity which completes the cure locally, and prevents subsequent grafts from holding.

It may be by absorbing the antibodies thus produced by the animal, that a large Jensen's rat sarcoma of the back renders more difficult the successful treatment of a coexisting tumour of the foot. For a similar reason it is hardly to be expected that absorption of a tumour of the left foot should invariably follow cure of a sarcoma of the right foot. The results may be dependent on the relative size of the tumours, &c.

In estimating the meaning of the above experiments it is to be appreciated that causing the disappearance of an inoculated and more or less encapsuled tumour is a very different thing from curing a spontaneous, invading, and metastasising new growth. It is further noteworthy that the conditions were to some extent favourable for success by reason of the site chosen for inoculation. In spite of these considerations the results do seem to indicate a hopeful line of inquiry.

Looking to the future it is proposed to try whether curative effects can be obtained by frequently repeated inoculation of cells damaged by culture in antiserum or of cells otherwise attenuated. Further, if the virus and specific factor for the existence of which Gye and Barnard have adduced evidence prove to be the veritable cause of cancer, then the antiserum may have other than purely cytolytic effects, and it may be possible to obtain a stronger and more specific antiserum by using these isolated factors as antigens than by employing the living cancer cells as I have done.

Conclusions.

1. An appropriate antiserum kills cancer or sarcoma cells in vitro, rapidly and invariably. It is much less toxic to the normal tissues than to the malignant cells. 2. Pieces of cancer tissue kept in antiserum for three to six days at 37° C. do not thereafter produce a progressive tumour when inoculated into the living animal. 3. Jensen's rat sarcoma of the foot can be caused to disappear by repeated injections of antiserum into and round the tumour, along with temporary stoppage of circulation in the foot. 4. After such removal of a tumour the rat becomes immune, so that a subsequent inoculation of Jensen's rat sarcoma into the other foot or into the axilla does not hold. 5. When an implanted tumour is growing on each foot, removal of one of these by means of antiserum and constriction is, in a large proportion of cases, followed by absorption of the tumour in the other untreated foot. 6. It is suggested that during absorption of the tumour after treatment with antiserum and constriction, the products absorbed from the attenuated or dying cells evoke a general active immunity which completes the cure and prevents subsequent grafts from holding. Such an antiserum might in this way prevent recurrence of a tumour after incomplete surgical removal.

My grateful thanks are due to Prof. C. J. Martin, F.R.S., for putting a laboratory at the Lister Institute of Preventive Medicine at my disposal and for never-failing help and advice in many directions. I have to thank also the British Empire Cancer Campaign for a grant which has enabled me to continue the experiments above recorded.

A CASE OF

CHRONIC NEPHRITIS WITH A POSSIBLE PARATHYROID SYNDROME.

BY C. R. BOX, M.D., F.R.C.P. LOND.,
SENIOR PHYSICIAN, ST. THOMAS'S HOSPITAL;
AND
O. L. V. DE WESSELOW, M.B. OXF.,
F.R.C.P. LOND.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS AND CHEMICAL PATHOLOGIST, ST. THOMAS'S HOSPITAL.

THE following case seems to us to be worthy of a detailed record, since, as far as we are aware, the findings cannot be paralleled in the literature, and since, in view of certain recent observations of Collip, which will be discussed later, the changes in the chemical composition of the blood are of considerable interest. Some details of the latter have been reported already by one of us[1] in a study of the calcium and phosphate content of the blood in nephritis, but in that communication numerous abnormalities presented by the patient were not touched on, and no clinical details were given.

Record of the Case.

The patient, a man of 37, gave no history of any previous illnesses with the exception of two attacks of enteritis while serving in France. He was admitted to hospital on Nov. 7th, 1922, as a suspected carcinoma of the stomach. He had then suffered from attacks of nausea and vomiting for about six months, attacks which had been increasing in severity during the ten weeks previous to admission, and which had led to considerable loss of weight and strength. The vomiting usually occurred three hours after meals and was not accompanied by any abdominal pain. No hæmatemesis or melæna had been noted; there was a doubtful history of jaundice at the onset. The patient also stated that nocturia and polyuria had been present for some years.

Condition on Admission.—An anæmic, wasted man, showing a fine tremor of the hands; no thyroid enlargement. Pulse 80–90. Arteries moderately thickened; apex beat 4 inches from the mid-line in the fifth space, a faint non-conducted systolic murmur present at the apex. Lungs, abdomen, and central nervous system—nothing abnormal. Urine sp. gr. 1010, acid, faint trace of protein, no sugar; deposit, red blood cells, hyaline and granular casts. The amount of urine passed tends to be excessive, frequently exceeding 2500 c.cm., and occasionally reaching a figure in excess of 4000 c.cm. Wassermann reaction negative.

Test Meal.—Free HCl 0·131, combined HCl 0·104, total 0·205—a result which could be taken as excluding gastric carcinoma.

During his stay in hospital the patient suffered from occasional attacks of vomiting and headache. He was at his worst from Dec. 11th, 1922, onwards, when a considerable degree of circulatory failure accompanied by a stuporous, semi-comatose condition developed. In the absence of an increase in the inorganic phosphate of the plasma uræmia was excluded, and the symptoms were attributed to the cumulative effect of chloretone, which had been administered to check the vomiting, in the absence of efficient renal elimination. With omission of the chloretone the patient slowly recovered. On discharge the patient had gained about a stone in weight, and the general condition had improved, though vomiting was still present on occasion. As will be seen from the accompanying table no improvement had occurred in the renal condition as judged by the urea-concentration test, though the blood-urea had fallen as the result of excessive diuresis.

Though on admission the urine showed no sugar, a reducing substance, identified by its osazone as glucose, was present at times from Jan. 21st, 1923, onwards. The amount of sugar present was small, averaging about 0·3 per cent. Tolerance curves to 50 g. of glucose gave the following figures:—

23/1/23. Before: Blood-sugar, 0·100 per cent. After: 30′, 0·100; 60′, 0·131; 115′, 0·125; 135′, 0·110.

8/2/23. Before: Blood-sugar, 0·101 per cent. After: 30′, 0·105; 60′, 0·112; 120′, 0·112.

The glycosuria was therefore attributable to a lowered renal threshold. The sugar tolerance appeared to be increased, the highest level met with in the course of the test being below that usually found in the normal. This point cannot, however, be stressed in view of the possibility of impaired absorption in a patient who constantly suffered from nausea.

Electrical reactions were normal. The basal metabolism gave a figure of + 26 per cent. (Feb. 9th, 1923). X ray examination showed no evidence of pituitary enlargement or atrophy, no changes in the consistency of the bones, and no arterial calcification.

Owing to a progressive weakness in the voice, the larynx was examined on Jan. 30th, and a complete paralysis of the right recurrent laryngeal was found to be present. The alkaline reserve of the plasma, estimated April 17th, 1923, gave a low normal figure—53 vols. CO_2 per 100 c.cm. of plasma.

The patient died three months after his discharge at Exeter, and no post-mortem examination was performed.

Conclusions.

We have, then, a patient presenting definite evidence of chronic azotæmic nephritis, and in addition an increased basal metabolic rate, a possible increase of sugar tolerance, and a recurrent laryngeal paralysis. Of the chemical findings the most striking is the abnormally high calcium content of the serum. The method employed in estimating the serum calcium was that of Kramer and Tisdall, a method which is usually accepted as sufficiently accurate for clinical use, and at the time at which these high figures were obtained numerous serum calcium estimations were being made upon other patients, in none of whom was a calcium content in excess of 11 mg. per 100 c.cm. of serum met with. In the individual under consideration the calcium at one time reached a figure of 20 mg.

This extraordinary variation of what is usually one of the most constant constituents of the blood naturally suggests an involvement of the parathyroids. Such an involvement would be of the nature of a hyperplasia, since parathyroidectomy leads to a fall in the serum calcium. Some confirmation of this view is to be found in the literature. MacCollum,[2] as long ago as 1905, reported a case of parathyroid hyperplasia, in which a tumour 2 cm. in diameter and composed of parathyroid tissue was found below the lower pole of the thyroid; the patient had suffered from a severe chronic nephritis of some years' duration. In another case of advanced chronic nephritis McCollum noted abundant mitoses in the parathyroids. Later Bergstrand[3] described hyperplastic enlargement of the parathyroids in ten cases of severe renal disease. None of these patients showed osteoporosis or osteomalacia, but deposits of lime salts were present in the kidneys. Barker[4] mentions a case studied by Thomas and Wentworth in which parathyroid hyperplasia was associated with chronic renal disease of ten years' standing. In this patient deposits of lime were present in the tendon sheaths and bursæ of various parts of the body, and an X ray examination showed extensive calcification of the smaller arterioles. At autopsy a considerable degree of bony softening was found to be present.

There appears, therefore, to be good evidence of a connexion between chronic renal disease and parathyroid hyperplasia, and of the possibility of a mobilisation of calcium salts in the condition. As far as we can discover, however, no previous records exist of an increase in the serum calcium in chronic nephritis; as a rule, the calcium of the serum is diminished in proportion to the degree of phosphate retention present.

Recently Collip[5] has studied the effects of an active extract which he has prepared from the parathyroid gland. By repeated injections he was able to raise the serum calcium of normal dogs to a level of 21 mg. per 100 c.cm. When the serum calcium exceeds 15 mg. symptoms of a condition which he describes as hypercalcæmia appear. These symptoms are weakness and atonia, diarrhœa and vomiting, circulatory impairment, extreme viscosity of the circulating blood, and ultimate collapse and death. The extreme viscosity of the circulating blood, which according to Collip makes it difficult to obtain blood even by venesection, was not noted in our case. The chemical changes in the blood that result from such injections are a great increase in the urea nitrogen, a gradual fall in the halogen content of the blood (which, it may be suggested, is a result of the vomiting), a terminal rise in the phosphate content, which is at first unaffected, and a pre-mortal fall in the alkaline reserve of the plasma. It is not as yet clear whether these changes result from a direct action on the kidney, or whether the primary circulatory failure leads to renal inadequacy with the above characteristic changes in the blood. It is, however, obvious that normal dogs may, after repeated injections of the parathyroid hormone, show a chemical blood picture resembling that seen in our patient.

The paralysis of the recurrent laryngeal is a readily conceivable pressure effect in parathyroid enlargement. The cause of the increased basal metabolism remains obscure. No evidence of hyperthyroidism was present, and the action of parathyroid on the basal metabolism does not appear to have been worked out. If the blood-sugar curves are accepted as evidence of increased sugar tolerance, such an effect is to be expected in parathyroid hyperplasia, since parathyroidectomy is reported to produce a diminished carbohydrate tolerance in animals. Salvesen[6] has shown also that in parathyroidectomised animals the carbohydrate tolerance curves rise as the serum calcium falls, and believes that a direct connexion exists between the serum calcium content and the capacity of the organism to deal with ingested carbohydrate. Attempts were made to reduce the serum calcium in our patient by administration of sodium bicarbonate, and di-sodium phosphate, but no definite results were obtained.

YATREN IN THE TREATMENT OF AMŒBIC DYSENTERY.

WITH A NOTE ON THE RESULTS OF STOVARSOL IN CERTAIN CASES.

BY PHILIP H. MANSON-BAHR, D.S.O.,
M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES;

AND

R. M. MORRIS, M.B., B.S. LOND.,
HOUSE PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES.

SINCE the introduction of emetine in the treatment of amœbiasis in 1912 various improvements in the therapeutics of amœbic dysentery have been made. It is now generally conceded that emetine injections, although temporarily successful, do not eradicate an amœbic infection from the bowel, even when administered in almost toxic doses. Hence emetine bismuth-iodide and its modification, emetine periodide, have been largely employed in the treatment of the disease and have proved themselves efficacious to a considerable extent in the acute, as well as in the chronic, stage with the passage of *E. histolytica* cysts.

There are several objections to the continued use of these emetine compounds; amongst others may be cited their nauseating and debilitating effects, the liability to develop symptoms of emetine intoxication, the very restricted diet upon which it is necessary for the patient to be placed, and to these may be added the general depressing after-effects, mental and physical, which too often result from their use. In a certain proportion of cases of chronic amœbic dysentery (variously estimated by different authorities) the organisms become resistant to emetine, and under these circumstances it appears to be useless to continue further emetine treatment with the idea of effecting a permanent cure.

The occurrence of emetine-resistant forms has been tolerably familiar to tropical practitioners since the end of the war, and it is for this class of case that Yatren was originally introduced by Mühlens and Menk in 1921.

Yatren ($C_9H_6O_4SNI$) is a combination of iodine with oxyquinoline-sulphonic acid with the addition of 20 per cent. sodium bicarbonate. The iodine is so firmly combined that it is not given off on boiling nor split off within the body of man, hence it cannot produce iodism. For the last ten years Yatren has been in use in Germany and Holland as a wound antiseptic and tissue stimulant. Under the name "Yatren Purissimum No. 105," it is manufactured by the Behring Institute, Marburg/Lahn, Germany. The drug, when given by the mouth or enema, is rapidly absorbed, and is to a great extent excreted in the urine, where its presence can be demonstrated five or six hours later by the addition of ferric chloride, with which it gives a green colour.

In the treatment of amœbic dysentery Yatren may be exhibited in one of three ways: in pill form, containing 0·25 g. (4 gr.), of which two are given twice daily; in cachet form of 0·5 g. (7½ gr.) twice daily by the mouth; or by enema of 200 c.cm. containing 3–6 g. of the drug given daily for 8–14 consecutive days. In 1921 Mühlens and Menk reported upon two extremely resistant cases of amœbic dysentery which had been completely cured by Yatren given by mouth and per rectum. Birt in Shanghai, in 1923, treated a series of 28 cases by lavage alone, using 100 c.cm. of a 10 per cent. solution twice daily, and he concluded that it was a good treatment, but not more efficacious than others previously in use; whilst in many, particularly in the freshly infected cases, the patients suffered much more from colic and tenesmus as a result of the injection. The criticism of his results by Menk is to the effect that the menstruum was too small in quantity and the concentration too great. In 1922 Kuenen published details of four cases all cured by Yatren given by the mouth in doses of 3 g. daily for 8–14 days. In the only paper on the subject in English, Gordon notes two cases treated by lavage which relapsed in a short time; the doses were those originally recommended by Mühlens and Menk. Recently a considerable amount of literature has accumulated round the subject, of which a number of references will be given at the end of this paper.

During the last six months we have had the opportunity of treating four typical cases of amœbic dysentery of different degrees of severity with this drug. We make a special point of stating that diagnosis and treatment have been controlled by sigmoidoscopic examination, a method which is more reliable than stool examination alone.

Clinical Reports.

The following are brief details of these cases.

CASE 1.—Ex-soldier, Indian infection; five months' duration; acute symptoms. Loss of 4 st. in weight (actual weight 9 st. 2 lb.). Stools, four to five a day, containing blood, mucus, and very numerous active free *E. histolytica*.

Sigmoidoscopy.—Mucous membrane of rectum appeared as an extensive bleeding ulcerated surface, the intestinal lumen being full of extravasated blood, constituting a picture of the most marked amœbic ulceration yet seen on sigmoidoscopic examination (P. H. M.-B.). General condition of patient poor.

Treatment.—Yatren 2½ per cent. solution; 200 c.cm. by enema daily for five days and then, after a four-day interval, a further similar course (10 treatments) and concurrently Yatren pills (1½ g. daily) for 19 days.

Results.—Entamœbæ disappeared from stools, which became formed and normal within four days. Sigmoidoscopy repeated 23 days after commencement of treatment; former ulcerated areas now appear as non-depressed diffuse granulating patches which do not bleed. No active ulceration seen. General condition much improved. After one month in hospital gained 18½ lb. in weight. Improvement maintained now for over four months on ordinary diet.

CASE 2.—Ship's cadet. Infection contracted in Mauritius. One and a half years' duration; acute symptoms; loss of 1½ st. in weight; stools four to five a day, diarrhœic, blood and mucus, free active *E. histolytica* in large numbers. Previously treated with injections of emetine, pulv. ipecac., bismuth and opium, &c.

Sigmoidoscopy.—Granular eroded patches in rectum and definite ulceration as far as could be seen. General condition poor.

Treatment.—Yatren 2½ per cent. solution; 200 c.cm. for six days together with Yatren pills (1½ g. daily) for ten days.

Results.—Entamœbæ disappeared from the stools, which became normal on the fifth day. Presence of Yatren demonstrated in urine. Sigmoidoscopy one month after treatment showed a few pin-point submucous hæmorrhages and scanty minute depressions in mucosa at site of former ulcerations; otherwise normal. General condition of patient much improved, gain of 1 st. in weight. Stools have been examined on five occasions during the last four and a half months since his discharge; general good health maintained; stools normal in number and consistency; no entamœbæ or cysts.

CASE 3.—Colonial official. Nigerian infection; two years' duration; acute symptoms off and on for one year; recently passed through an attack of amœbic hepatitis. Loss of 3½ st. in weight. Stools five a day with blood and mucus and active free *E. histolytica*.

Sigmoidoscopy.—Typical diamond-shaped amœbic ulceration of rectum extending to anus. General condition of patient poor.

Previously Treated.—In hospital on two occasions for same condition. Had received 42 injections of emetine (gr. 1 each), also 90 gr. of emetine in Nigeria; 72 gr. of E.B.I. (two courses); 52 gr. of E.P.I. and other drugs. On each occasion relapse occurred with passage of typical stools within three weeks.

Present Treatment.—Yatren 4 per cent. solution, 200 c.cm. by enema daily for ten days (i.e., 80 g. of Yatren) together with 1½ g. by mouth daily in pill form for three weeks.

Result.—Remarkable improvement in general condition; gained 2 st. in weight within six weeks of cessation of treatment; states "Since course of Yatren I feel an entirely different person." Stools one daily, formed, and on 11 examinations in two months after cessation of treatment were negative for amœbæ or cysts. Has now returned to Nigeria in good health.

CASE 4.—Business man. Infection in Cape Verde Islands; 2½ years' duration; acute relapses from time to time during that period. Acute symptoms on admission. Loss of weight about 1 st.

Stools.—Diarrhœic, two a day, blood and mucus, free active *E. histolytica*.

Previous Treatments.—3½ gr. of emetine; 10 gr. of E.P.I., 1 g. of N.A.B., and potassium permanganate lavages.

Present Treatment.—Yatren 2½ per cent. solution; 200 c.cm. for six days.

Sigmoidoscopy.—At end of treatment showed healing and granular patches in rectum.

Gain of weight 9 lb. during treatment; general improvement. Six weeks after cessation of treatment: no acute symptoms, but cysts of *E. histolytica* were found on examination of stool. Course of E.B.I. subsequently given with resultant disappearances of cysts. Good health and improvement maintained for last three months.

Summary.

The results may be summarised thus. The first three cases may be considered as uniformly satisfactory, whilst the fourth is less so, but was only incompletely treated with Yatren, the eradication of the infection being subsequently brought about by E.B.I. To those who have studied the details of the above protocols, we would like to point out that the rapidity with which Yatren acts in the acute stage of the disease is remarkable, amœbæ being apparently destroyed in four days after the injection of Yatren by enema.

In our opinion, in order to get the maximum effects, the drug has to be administered per rectum, as well as by mouth. To do this successfully, the bowel has to be previously washed out with a 2 per cent. solution of sodium bicarbonate about one-quarter of an hour before the injection of Yatren, which must be done slowly by means of a funnel and tube. The solution is then retained as long as possible and then voided. In our cases the average time of retention was about eight hours, occasionally as long as 12 hours. No toxic disturbances appear to be produced by the absorption of the drug.

Yatren is said, by many writers on the subject (Mühlens and Menk, and others), to produce a specific diarrhœa, but in cases of amœbic dysentery we have not encountered this phenomenon, though in other bowel conditions, such as ulcerative colitis and chronic bacillary dysentery in which we have also given it a trial, it readily does so.

Conclusions.

Yatren is of definite therapeutic value in the treatment of amœbic dysentery. Our cases are limited in number, but were all very typical examples of the disease. The results have been most gratifying and are apparently permanent. From the patient's point of view Yatren therapy is more pleasant than any yet evolved, the toxic effect being almost negligible, and there being no necessity to restrict the patient's diet unduly. As the drug is not nauseating our patients have been on a diet of fish, eggs, milk and milk puddings, and toast throughout their course of treatment. (Case 3.)

NOTE ON TREATMENT OF CASES WITH STOVARSOL.

One great difficulty in the effective treatment of amœbiasis is the chronic cyst-passer, or the man who continues to excrete cysts of *E. histolytica* subsequent to the cessation of acute symptoms. For this purpose we have recently been exhibiting tablets of stovarsol, as recommended by Marchoux. This drug is given in 4-gr. tablet by the mouth, and has been used in the treatment of syphilis; it is an acetyl-oxy-amino-phenyl compound of arsinic acid. A considerable amount of literature has accumulated round this drug, and it appears to be especially adapted for the symptomless cyst-passer who cannot, or will not, undergo a drastic course of E.B.I. treatment. One tablet of the drug is taken after breakfast daily for 14 consecutive days in two courses with an interval of a week's duration between them, so as to avoid any possible manifestation of arsenical intoxication. Two medical officers, who were cyst-passers, have been treated in this manner recently. The cysts disappeared from the stools after the first week of treatment, and we concluded that the use of stovarsol as an after-treatment is to be recommended, its value being probably due to its tonic effects.

Quite recently we have had the experience of two good cases of relapsing amœbic dysentery, who proved to be particularly resistant to E.B.I., so that their eventual recovery may be ascribed to stovarsol.

CASE 1.—The patient had been under observation for 2¼ years. Had had four attacks of acute amœbic dysentery including one relapse with hepatitis. His treatments had consisted of five courses of E.B.I. of 36 gr. each; two courses of E.P.I., and over 100 gr. of emetine. During his last relapse he was exceedingly ill and lost over 1 st. in weight. Since October, 1924, he has taken stovarsol in two courses of 8 gr. daily. During the recent period of observation, since the beginning of 1925, his health has much improved, his weight has increased by 42 lb., and his stools are normal and consistently negative for amœbæ and cysts.

CASE 2.—Infection contracted 1922 in Java, where he was treated with emetine, E.B.I., and ipecacuanha. In England in June, 1924, an acute relapse occurred for which he was treated with 24 gr. of E.B.I.; relapsed again four months later, and he was then given stovarsol in large doses of 12 gr. daily for 14 days and subsequently 1 tablet daily for two months. Since then he has been free of symptoms, the stools have been examined at intervals on five occasions, and when last seen in May, 1925, was in good health and has regained his normal physical condition.

Conclusions.

We may thus regard stovarsol as an adjuvant of considerable value in the treatment of amœbiasis. We have no evidence that it acts as a direct amœbicide, but it has a definite therapeutic value in the chronic stage of the disease, and may be recommended in those cases which are resistant to or intolerant to emetine and its compounds. As toxic symptoms due to absorption of arsenic are apt to occur, the dose of 2 tablets daily (gr. viii.) for one week, or 1 tablet daily (gr. iv.) for 14 days, should not be exceeded.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BATH.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

THIS Section met on three days under the presidency of Sir Maurice Craig.

WEDNESDAY, JULY 22ND.

Causation and Symptomatology of Multiple Neuritis.

In opening a discussion on this subject, Dr. T. Grainger Stewart (London) defined cases of multiple neuritis as "those in which, as the result of a general cause—toxic, infectious, or metabolic—the symptoms present pointed to a more or less simultaneous affection of many of the peripheral nerves, or of their associated peripheral neurones." By this definition all cases of neuritis directly due to local traumatism or compression were excluded, but not those in which the neuritis arose as the result of the general action of a toxin, developed locally in connexion with a local lesion. Further, it permitted the inclusion of cases in which the peripheral neurones, rather than the peripheral nerves proper, were involved. Dr. Grainger Stewart considered it quite impracticable in the present state of our knowledge to attempt to classify multiple neuritis on any other than an ætiological basis, as although the clinical picture in certain forms of multiple neuritis was distinctive, in the majority of cases no clinical differentiation was possible. He would, therefore, classify the different forms as follows:—

(A) *Exogenous Poisons.*—Lead, arsenic, mercury, &c.; alcohol, carbon monoxide, carbon bisulphide, serum disease, &c.

(B) *Endogenous Toxins.*—(1) Metabolic: Diabetes, beri-beri, hæmatoporphyrinuria, and during pregnancy. (2) Cachectic: Malignant disease, senile, chronic anæmia, &c. (3) Infective: (*a*) In association with acute infective fevers, &c.—typhoid, paratyphoid, &c.; tubercle, syphilis, &c. (*b*) In certain epidemics—e.g., influenza. (*c*) Infective disease in which the neuritis was an essential part of the clinical picture—uveo-parotitic paralysis, pink disease. (*d*) Infections in which the toxin had a special affinity for the nervous system—e.g., diphtheria. (*e*) In acute, subacute, or chronic infections whose incidence was chiefly on the nervous system—acute toxic polyneuritis, acute febrile polyneuritis, acute infective polyneuritis, Landry's paralysis, and recurrent multiple neuritis.

(C) *Multiple Neuritis of Obscure Origin.*—Rheumatic.

(D) *Local Infections of Nerves.*—Leprosy, interstitial hypertrophic neuritis: (1) juvenile (Dejerine-Sottas), and (2) adult (Dide and Courjon).

The two principal factors which determined the mode of onset and the distribution of the symptoms were: (1) the selective action of the poison, and (2) the distribution of the poison within the nervous system. It was known that the nervous system had the property of fixing certain toxins, such as those of tubercle, diphtheria, and tetanus, owing to a special chemical affinity. The distribution of the toxin was also influenced by the selective factor, and its incidence was determined in the first place by the paths along which the toxin reached the nervous system. There were two such paths: (1) the blood, and (2) the nerves (perineural lymphatics).

In dealing with the various forms of multiple neuritis the opener referred chiefly to three of that group due to exogenous poisons—viz., the neuritis of alcohol, lead, and arsenic. Alcoholic neuritis was now more rare than formerly, and appeared to be more frequent in spirit-drinkers than those addicted to beer. The characteristic features in all cases of alcoholic neuritis were: (1) The severity of the pain and sensory disturbances; (2) the acute tenderness of the nerves and muscles; (3) the tendency for the lower limbs to be affected earlier and more severely; (4) the weakness predominating in the extensor muscles; (5) the rapid onset of contractions and deformities; and (6) the occurrence of mental changes of a typical character. The latter—known as "Korsakow's psychosis"—consisted in an amnesia for recent events combined with a disorientation in space and time. With regard to lead neuritis, the palsy was only one of the manifestations of lead poisoning. The special features were: (1) The absence of sensory symptoms—apart from muscular cramps; (2) the nerve trunks were not tender; (3) the upper extremities were more affected than the lower and the palsy was often confined to certain groups of muscles; and (4) other evidences of lead poisoning were present—anæmia, colic, blue line in the gums, and vascular changes. Various clinical types had been described, among which were: (1) The antebrachial type (Remak)—seventh cervical, in which the extensors of the wrist and fingers, the extensor and long abductor of the thumb were paralysed, causing drop-wrist. The supinator longus muscle—innervated from the fifth cervical root—generally escaped. (2) The Aran-Duchenne type—eighth cervical and first dorsal—characterised by weakness and wasting of the intrinsic muscles of the hand; and (3) the Duchenne-Erb type—fifth and sixth cervical, in which the dorsal, biceps, brachialis anticus, and supinator longus were chiefly affected. The clinical picture in lead palsy, therefore, pointed to an affection primarily of the lower motor neurone and its segmental or radicular distribution to a neuronic rather than to a neuritic affection. Apart from the occurrence of arsenical poisoning, accidental or intentional, the condition might arise from the prolonged use of arsenic in the treatment of chorea or the severe anæmias. All four extremities were wholly affected, while severe sensory disturbances, trophic changes, falling of hair, hyperkeratosis, and pigmentation were characteristic features.

The most important of the metabolic group was the neuritis of diabetes, and it was present in about 50 per cent. of cases of that disease. Sensory symptoms predominated, and examination showed that the deeper forms of sensation were more affected than the superficial. It was rare to find complete paralysis, but definite muscular weakness was easily demonstrable; the lower extremities were more often affected than the upper. Multiple neuritis had been found in association with most of the well-known varieties of infectious disease, either during the course of illness or supervening upon it. Diphtheria provided us with an example of multiple neuritis occurring in an organismal infection developing its local lesion on a surface of the body, and at the same time evolving a toxin with a selective action on the nervous system. Paralysis occurred in about 20 per cent. of cases. Experiment had shown that antitoxin would prevent paralysis and statistics that no multiple neuritis occurred in those cases in which the bacilli were destroyed early. It was only when the local lesions had been missed or neglected that severe paralysis followed a mild infection.

To the group which he had termed "acute, subacute, and chronic infections with incidence chiefly on the nervous system," Dr. Grainger Stewart proposed to add Landry's paralysis. In Landry's paralysis the onset might be abrupt with ascending paralysis commencing at the periphery of the lower extremities—ascending even to the facial muscles provided death had not resulted from respiratory paralysis. The paralysis was flaccid, painless and sensory disturbances rarely exceeded a mild paræsthesia in the extremities. In some cases the onset was less abrupt and the paralysis might be of a descending type or even appear to spread from the site of onset both upwards and downwards. If we compared this with the descriptions of acute febrile or acute infective polyneuritis given by Bradford, Bashford and Wilson, and by Holmes, we found no material difference. Extending from the toes upwards, the paralysis affected the trunk muscles, arms, and face, the facial palsy—although sometimes of slight degree—being a characteristic feature. Sensory changes had not been marked.

Dr. Grainger Stewart said he had seen several cases of Landry's paralysis and over 20 cases of acute toxic polyneuritis. In some of the latter the diagnosis was based solely upon the development of sensory disturbances 10 to 14 days after the onset of the paralysis; had death occurred before, they would certainly have been accepted as being typical of Landry's original description. Now, in all these cases we had the following resemblances: (1) An acute ascending paralysis of flaccid type with abolition of deep reflexes; (2) a febrile onset; (3) only slight disturbances of sensibility; (4) transient interference with sphincters; (5) absence of mental changes. Cases of recurrent multiple neuritis had been described. The symptoms were predominantly motor, each attack left the patient weaker than before, there was more wasting than was usually found in multiple neuritis, and the attacks occurred without known cause at irregular intervals. In view of all facts, it was no longer possible, he said, to limit our conception of multiple neuritis to one in which the peripheral nerves alone are affected. We should think in terms of neurones, as it was illogical to separate a nerve cell from its fibres; they were essentially one from the point of view of function, and interference with either must, and does, affect both.

Discussion.

Dr. Wilfred Harris (London) commented upon classification and considered that Dr. Grainger Stewart's groups (*c*) and (*d*) would probably fall into either the "Exogenous poison" or the "Endogenous toxin" group. Leprosy did not appear to him to be a cause of multiple neuritis. Korsakow's psychosis also occurred in connexion with neuritis other than that due to alcohol, and multiple neuritis might develop from local septic wounds apart from diphtheria. With regard to the alleged neuritis of serum disease, he thought that such neuritis was more likely to be a result of the infective disease for which the serum was given rather than of the serum itself; during the war, while acting as a tetanus inspector, he had seen many serum-treated cases and had met with no neuritis as a result. Dr. Harris disagreed with Dr. Grainger Stewart that lead neuritis was segmental in distribution, the radial extensors were innervated not from the seventh cervical segment but mainly from the sixth and even the fifth. The Aran-Duchenne type, he considered, was due to chronic anterior poliomyelitis, and, as distinct from wrist-drop, was permanent and incurable.

Dr. W. Johnson (Liverpool) dealt with certain atypical forms of lead neuritis which did not appear to harmonise with the theory of the selective action of the toxin and compelled us to seek an additional explanation. Fatigue might be a contributory factor.

Edinger, of Frankfort, originally advanced the view that in a condition in which toxins are circulating through the system the poisoning effects are liable to occur chiefly in those structures which have been the seat of fatigue. The ordinary painter used a free flexion and extension movement at the wrist in performing his work; the extensors were at a mechanical disadvantage as compared with the flexors and were therefore more susceptible to fatigue. The right arm was more commonly affected, but if the patient were left-handed, then the left arm showed the more marked paralysis. In the occupation known as "puddling" a heavy scraper was used which threw considerable strain on the shoulder muscles. In such cases the upper arm type of lead palsy was the more common.

Dr. F. J. Nattrass (Newcastle-on-Tyne) drew attention to the occasional occurrence in cases of multiple neuritis of enlargement and hardening of the nerves. He had met with two such cases. Portions of the musculo-cutaneous nerve of the leg and the great auricular nerve were examined microscopically; some hundreds of serial sections revealed no anatomical changes beyond some œdema of the nerve sheath. In a longitudinal section of a portion of the great auricular nerve, however, a pre-capillary venule in the adventitial tissue at some distance from the nerve showed perivascular infiltration with large mononuclear cells.

Dr. S. A. Kinnier Wilson (London) agreed with the opener that in many cases the term "multiple neuritis" was a misnomer since changes were found not only in the nerve trunks but also in the nerve cells and muscles. Further, sensory changes might be entirely absent. A better term for such cases was "polyneuronitis." The speaker was not impressed by Edinger's theory of fatigue. He also referred to the condition known as "central neuritis"—really a neuronitis—in which the medullated fibres of the central nervous system were affected.

Dr. C. Worster-Drought (London) referred to the occasional occurrence of nystagmus in polyneuritis, and particularly in the alcoholic form; a case of the latter disease showing pronounced nystagmus was under his care at the present time. With regard to a question raised by Dr. Grainger Stewart, the speaker had seen the neuritis of diabetes improve pari passu with improvement in the diabetic symptoms both on dietetic treatment alone and with insulin. Syphilitic neuritis was an interesting though somewhat rare form of polyneuritis—or more strictly, polyneuronitis, since sensory changes were usually absent. The condition, when present, usually appeared late in the secondary stage and with suitable treatment the prognosis was exceedingly good. Dr. Worster-Drought also described a case of recurrent multiple neuritis which he had observed over a period of two years; the onset and each recurrence was ushered in by acute gastro-enteritic symptoms The case had been fully investigated from the clinico-pathological standpoint but, apart from certain blood-cell changes, with negative results.

Dr. A. F. Hurst (New Lodge Clinic) raised the question of latent peripheral neuritis. Absent ankle-jerks, he considered, might be the only sign of alcoholism. Such cases could be distinguished from early tabes dorsalis, as in the latter disease the calves were analgesic, whereas in alcoholic neuritis they were very tender. It was very rare to find alcoholic neuritis and cirrhosis of the liver coexisting; indeed, they appeared mutually exclusive. In alcoholics who died of cardiac failure it was often surprising what few changes were found in the heart muscle on post-mortem examination; the cardiac disorder, he considered, was largely due to a disturbance of the vagus nerve. In certain cases of beri-beri Dr. Hurst considered that in addition to vitamin deficiency as an ætiological factor there was an infective agent. In the Gallipoli campaign, for instance, beri-beri was often accompanied by jaundice; in these cases the duodenum was found post mortem to show evidence of inflammation.

In the unavoidable absence of Dr. J. S. Collier (London) his observations were read by Dr. E. Mapother. Dr. Collier considered it peculiarly fitting that Dr. Grainger Stewart should open the discussion on multiple neuritis, since it was his father—Sir Thomas Grainger Stewart—who wrote the first English monograph on the subject 45 years ago. Dr. Collier also mentioned the occurrence of nystagmus in polyneuritis, and thought the phenomenon was due to involvement of the cerebellar neurones. The lesions of multiple neuritis were not necessarily symmetrical; he had seen cases of both lead and alcoholic neuritis which were strictly unilateral. He was glad to see Landry's paralysis placed in its proper position as a polyneuritis by Dr. Grainger Stewart. Lastly, Dr. Collier referred to cases of neuritis due to the too enthusiastic and unduly prolonged administration of bacterial vaccines.

The President of the Section observed that it was important to examine the mental aspect as well as the physical in many forms of peripheral neuritis; minor mental changes in such cases often passed unrecognised. He pleaded for just as much care to be devoted to the mental examination as was given to the motor and sensory signs.

Prof. Edwin Bramwell (Edinburgh) emphasised the fact that in many cases of acute polyneuritis the ætiology was most obscure. In many cases, he believed, there was more than one active ætiological factor—e.g., an attack of influenza might determine the onset of neuritis in a victim of lead poisoning. He also referred to the occurrence of polyneuritis in association with hyperemesis gravidarum and described a case which showed the usual signs of multiple neuritis together with nystagmus and bilateral facial paralysis; later a Korsakow's psychosis developed. In the causation of some obscure cases there might be a food factor, the patient being unable to digest and absorb the necessary vitamins.

THURSDAY, JULY 23RD.

The Treatment of Insomnia.

Dr. Robert Hutchison (London), opening a discussion on this subject, said that for the purposes of treatment he divided cases of insomnia into two groups, (1) secondary, and (2) primary. In the secondary group the insomnia was the result of some physical discomfort—such as pain, dyspnœa, cough, flatulence, &c. The primary or intrinsic cases arose either from some psychical discomfort (worry, anxiety, &c.) or they were originally secondary cases, in which the physical cause having disappeared, the insomnia persisted largely as the result of auto-suggestion.

1. *Secondary Insomnia.*—The treatment of the secondary cases was primarily that of the associated disease. There could be no objection to the use of hypnotics in these cases from the fear of establishing a habit, as we were usually dealing with a disease of short duration in which the promotion of sleep was essential for the maintenance of the patient's strength and powers of resistance. When the insomnia was due to pain, analgesic drugs—aspirin and pyramidon—should be tried before morphine. In sleeplessness from dyspnœa, the hypnotic used depended upon the cause of the dyspnœa. For cardiac cases there was no drug to equal morphine, but in dyspnœa of pulmonary origin—e.g., bronchitis—it was contra-indicated. In such cases opium might be given in the form of Dover's powder; strychnine and oxygen were useful adjuvants. Pneumonia was a disease in which insomnia often resulted from a variety of factors—pain, fever, cough, dyspnœa, and toxæmia all playing a part. In the early stages—before the fifth day—morphine was much the most effective agent for promoting sleep; after the fifth day, however, it was rarely safe to use morphine, and opinions differed as to the most suitable hypnotic. Chloral was effective, and in Dr. Hutchison's opinion the depressing effect of this drug on the circulation had been exaggerated. Paraldehyde was safe but uncertain in its action; a dose of at least 2 drachms was required to produce an effect. For allaying

STUDENTS' GUIDE—SESSION 1925-26.

DENTAL SURGERY.

(Concluded from p. 519.)

TEACHING INSTITUTIONS IN DENTISTRY.

OF teaching institutions those connected with the several universities have now been described in some detail, but in addition to these there are a number of institutions which offer facilities to dental students and which are here set out under their localities.

LONDON.

Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.—A school of the University of London. Women are now admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for four months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £25. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25, open to pupils of the Hospital only. One Entrance Scholarship of £25 in Dental Mechanics, open to pupils of private practitioners. The Saunders Scholarship of £20 and Saunders Prize of £5 awarded to second year students. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Alfred Woodhouse Scholarship of £35 and the Robert Woodhouse Prize of £10 for Practical Dental Surgery. The "Lonnon" Bursary of £25 for second year students. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses at the end of the summer and winter sessions. Fee for two years' hospital practice required by the curriculum, including lectures, £70 in one payment, or £78 10s. in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £52 10s. Both hospitals can be attended simultaneously. For the lectures in Chemistry and Physics for the Preliminary Science or Pre-Medical Examination £13 13s. The fee for the instruction in Dental Mechanics and the two years' hospital practice required by the curriculum is £200 if paid in one instalment, or 200 guineas if paid in three equal instalments. The fee for tuition in Dental Mechanics is £70 per annum; for one year's hospital practice £28. The Winter Session opens on Oct. 1st.

University College Hospital Dental School, corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the National Dental Hospital, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. A calendar containing full information as to lectures, fees, prizes, &c., may be had on application to the Sub-Dean for Dental Students, who attends the Hospital on Monday mornings at 10 o'clock.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for ordinary extractions and anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrator, the dental house surgeon, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It has a floor space of over 6000 square feet, and affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type, for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by two demonstrators and five mechanics. Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Two Entrance Scholarships are awarded in July of each year, a War Memorial Scholarship in Arts of the annual value of £40 for four years; and a Jun'or Science Scholarship of the value of £40 per annum for not more than four years. Prizes of the aggregate value of £40 are awarded for general proficiency and for skill in Operative Dentistry. The Newland-Pedley Gold Medal for Operative Dentistry is also awarded annually. Dental students are eligible for admission to the Residential College and enjoy the privileges of students in the Medical School. Application should be made to the Dean of the Medical School.

Appointments: All appointments are made according to the merits of the candidates, as determined by a committee of the Dental Staff. Eighteen house surgeons, 15 assistant house surgeons, and 15 clinical assistants, and four student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, orthodontia dresser, casualty dresser, clerk to the anæsthetist, dresser in the gas extraction and ordinary extraction rooms, and probationary dresser.

King's College Hospital.—The Dental School is part of the Medical School of King's College Hospital, and was opened in November, 1923. The Dental Out-patient Department of the Hospital is used for the performance of dental extractions. A large Conservation Room with provision for 40 dental chairs has been equipped. Smaller rooms are used for clinical teaching and administrative requirements, and a specially equipped laboratory for training in the art of dental mechanics. An X ray apparatus has been installed for special use in dental skiagraphy. A museum containing a large number of specimens illustrating oral, buccal, dental, and other diseases is available for teaching purposes. The library, lecture theatre, lecture rooms, common rooms, and the refreshment room are all available for the use of students. Courses of study, including practical work, are provided for the degree of Bachelor of Dental Surgery of the University of London, and for the Diploma in Dental Surgery of the Royal College of Surgeons of England. Special arrangements are made for those students who wish to take a medical degree or qualification in addition to a degree or diploma in Dental Surgery. Full particulars of the Dental School may be obtained on application to the Dean, Dr. H. Willoughby Lyle, or to the Secretary, Mr. S. C. Ranner, M.A., King's College Hospital, Denmark Hill, London, S.E. 5.

London Hospital.—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the B.D.S. Degree and for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoons at many of the chairs have been specially designed. Each spittoon has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses in addition to the Theatres, Laboratories and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Metallurgy and Prosthesis. A systematic course of instruction is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to Scholarships and Prizes, fees and course of study advised, apply to the Dean, Prof. William Wright, who will be glad to make arrangements for anyone wishing to see the Dental School and Medical College.

London (Royal Free Hospital) School of Medicine for Women.—Full courses are arranged for women students, in conjunction with the Royal Dental Hospital, Leicester-square, for the study of dentistry, and in preparation for the B.D.S. Degree of the University of London and the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women.

PROVINCIAL.

Birmingham Dental Hospital, Great Charles-street.—Dean: Mr. W. T. Madin. The Dental Hospital was founded in 1858, and was recognised by the Royal College of Surgeons in 1880 for the teaching of Dental Students. Having an annual attendance of about 21,000 patients, it affords every advantage for students about to enter the profession to acquire a thorough practical knowledge, as required by the Medical Council. The present Hospital was opened on July 6th, 1905. It has accommodation for 100 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery. The operations performed annually average 41,000, including 9000 gold and other fillings, and many cases of crowns, bridges, porcelain inlays, and regulations. By arrangements with the Birmingham University and with the General and Queen's Hospitals the entire course of Lectures, Hospital Practice, &c., may be completed for an inclusive fee of £144 4s. 6d., or including Mechanical Pupilage, £255 15s. 9d., inclusive of Examination fees for L.D.S. Birm. The instruments and materials necessary for Hospital Practice cost about £45. The Composition Fee for the courses required for the L.D.S. of the University, or any of the Corporations alone, is £75, payable in two annual instalments at the commencement of the first and second years; that for the courses required for the L.D.S. and the Degree in Dentistry of the University is £93 15s.; that for the L.D.S. in combination with the M.R.C.S. and L.R.C.P. is £115; and that for the M.B., Ch.B., and B.D.S. is £120. All of these composition fees are payable in two annual instalments at the commencement of the first and second years. Each of these fees covers the cost of the courses given at the University for the qualifications indicated, but does not include fees for Hospital teaching, nor Pre-Dental year Chemistry and Physics. For two years' dental hospital practice the fee is £26 5s., payable in two instalments of £13 2s. 6d. each at the commencement of the first and second (hospital) years respectively. For two years' mechanical pupilage, £111 11s. 3d., which may be paid in two annual instalments of £65 12s. 6d. and £45 18s. 9d. respectively; mechanical pupils may join for a probationary period of one month, fee £6 11s. 3d., which is deducted upon payment of the full amount. For general surgical hospital practice, lectures, and demonstrations: Surgery, two winters, £13 2s. 6d. A Dental Scholarship is offered annually of the value of £37 10s. It is awarded to the student who, entering for the Dental Degree of the University, shall pass the best examination in the subjects studied during his apprenticeship. Application for admission must be sent to the Dean of the Medical Faculty, Mr. William F. Haslam, on or before Sept. 1st.

Leeds University School of Dentistry.—The School of Dentistry is adequately equipped to provide for the complete training of the dental student. The School forms a part of the Leeds School of Medicine, whilst the instruction in clinical and mechanical dentistry is carried out in the Dental Hospital at the General Infirmary. The courses of study are mainly designed to meet the requirements of the B.Ch.D. and L.D.S. Leeds, but every opportunity is afforded to students preparing for the degrees or diplomas of other licensing bodies. Full-time demonstrators give the instruction in clinical dental surgery and prosthetic dentistry, which is carried out under the supervision and direction of members of the Honorary Staff, two of whom are in attendance each day. Special facilities are provided for instruction in Orthodontia and Dental Radiography. Prizes are offered for competition to pupils and students in their respective years of study. Communications should be addressed to the Warden, School of Dentistry, The University, Leeds, from whom a prospectus may be obtained.

Dental Hospital of Manchester.—This hospital is in association for teaching purposes with the University of Manchester and the Royal Infirmary, and is in the centre of a very large population. Courses of study are provided to meet the requirements of the various examining bodies, including those of the University of Manchester for the qualifications L.D.S. and B.D.S., and the L.D.S. of the Royal College of Surgeons of England. Clinical instruction is given in Dental Prosthetics, Operative Dentistry, Diagnosis and Extraction, Orthodontics, Dental Surgery, Radiography, and Anæsthetics by specially appointed Clinical Teachers.

For the whole course of hospital instruction for the L.D.S. (including two years' mechanical training) the fee is £131 5s., paid in instalments. For the two years' Operative Course only, £26 5s., paid in two instalments. For the whole course of hospital instruction for the B.D.S. degree (including mechanical training), £168, paid in instalments. In accordance with the new regulations, L.D.S. students who have taken two years' training in practical Dental Mechanics with a registered practitioner are required to take a further year in the Hospital mechanical laboratory, the fee for this being £63. All the courses of instruction are open to women students. Copies of the Prospectus will be forwarded on application to Mr. J. Hilditch Mathews, Dean.

Newcastle-upon-Tyne Dental Hospital and School.—This hospital is centrally situated (within five minutes of the various colleges, infirmary, and railway station); the rooms are well lighted and thoroughly equipped for carrying on the work. Dental surgeons and an anæsthetist attend each morning. A tutorial dental surgeon and a prosthetic tutor is also in attendance. The Composition Fee for the special Dental Lectures and Dental Hospital Practice is £60 4s. if paid in one sum, or £62 6s. if paid in two instalments of £31 3s. The Composition Fee for the Lectures at the Colleges of Medicine and Science is £67 10s.; in addition to this there is a library and an athletic club fee. The fee for General Hospital Practice at the Royal Victoria Infirmary, Newcastle-upon-Tyne, is £23 2s. Medals and Certificates of Merit are granted to students showing certain standards of proficiency in the various classes at the Dental School. The prospectus of the Dental Hospital and School, containing full information, may be obtained from either Mr. J. T. Jameson, 13, Windsor-crescent, Newcastle-upon-Tyne, Dean, or Mr. James Coltman, 18, Ellison-place, Newcastle-upon-Tyne, Vice-Dean.

Devon and Exeter Dental Hospital, 24, Southernhay West, Exeter.—Established 1880.—The hospital is open on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, and patients are admitted between the hours of 9.30 and 11 A.M. Students attend the practice of the hospital under the control of the medical officers. Honorary treasurer, Mr. J. M. Ackland; secretary, Mr. Albert G. Littlejohn.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street, and offers special advantages to dental students. A large and important extension of the existing buildings is now in process of construction. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. The cost of the hospital outfit of instruments is included in the Dental Hospital fee of £42. The minimum cost of classes and Diploma for the whole course of dental instruction amounts to £118 10s. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The *minimum* cost of Professional Education, the Triple Qualification, and the Licence in Dental Surgery amounts to £107 8s. 6d. The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital, 158, Renfrew-street and 15, Dalhousie-street, Glasgow.—The School is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, Radiology, Anæsthetics, and Dental Materia Medica. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extra-mural schools where special provision is made for Dental Students. Composition fee for two years' Hospital Practice and Lectures special to Dentistry, £60 on entry, or in two instalments of £35 and £30. A new mechanical laboratory with bench accommodation for 60 pupils and fully equipped with the most modern appliances for teaching practical dental mechanics has recently been added. Fee for two years' tuition, £63, or in two instalments. Full information may be had on application to the Dean.

Glasgow Royal Infirmary (Dental Department).—Mr. W. R. Taylor attends at the Royal Infirmary at 9 A.M. on Wednesdays and other days as arranged. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital.

IRELAND.

Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.—All Dental Students who have passed their First Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica, and instruction in Anæsthetics. Fees: Hospital Practice (each year), £18 18s.; Lectures, £5 5s. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs.: E. S. Mellor to *Kellett*; H. L. P. Peregrine, A. Craig, C. N. Ratcliffe, J. F. Haynes, K. A. I. Mackenzie, G. Aubrey, R. E. Rampling, and H. L. Douglas to *President*, addl., for five months' course of instruction.

Surg. Lt.-Comdr. L. F. Strugnell, R.N., has been awarded Sir Gilbert Blane's Gold Medal, he having obtained a first-class certificate at the examinations held in 1925 for promotion to the rank of Surgeon Commander.

ROYAL AUSTRALIAN NAVY.

Surg. Comdr. W. J. Carr to *President*, addl., for five months' course of instruction.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. D. Bertram to *Ajax* for 28 days' training.

D. R. W. Burbury entered as Proby. Surg. Sub-Lt., and attached to the London Division.

ROYAL ARMY MEDICAL CORPS.

Temp. Capt. R. C. H. Francis relinquishes his commn. and retains the rank of Capt.

The undermentioned Lts. (on prob.) are confirmed in their rank: R. A. Bennett, W. H. Carter, W. D. Speedy, W. A. D. Drummond, J. G. E. Vachell, J. N. Atkinson, J. D. Corner, and J. T. Smyth.

ROYAL AIR FORCE.

Flight Lt. T. P. Harpur resigns his temp. commn.

COLONIAL MEDICAL SERVICE.

Dr. J. A. Beamish, medical officer, West African Medical Service, serving in the Gold Coast, has been appointed to be a Senior Medical Officer in Nigeria, with effect from Feb. 13th, 1925, in succession to Dr. T. M. R. Leonard, D.S.O., promoted to be Assistant Director of Medical Services in that colony.

Special Articles.

INTERNATIONAL CONGRESS OF CHILD WELFARE.

THE first International Congress on Child Welfare, as noted in THE LANCET last week (p. 509), was held at Geneva from August 24th to 31st. It was presided over by Mr. André Oltramore of Geneva, and was well attended; over 800 delegates from all parts were present, including some 200 British representatives. The inaugural meeting was opened by Mr. Haeberlin, Vice-President of the Swiss Federal Council. The speakers included Prof. C. Pirquet (Vienna), the President of the Hygiene and Medicine Section, Mr. Georges Scelle (professor of international law at Dijon), President of the Social Welfare and Administration Section, and representatives of 12 other countries. The Marchioness of Aberdeen and Temair, speaking as President of the Education and Propaganda Section, referred to the work done by the International Council of Women (of which she was the President) in drawing up the declaration of the rights of the child, now called the Declaration of Geneva. Dr. Luis Morquio, the provisional director of the American International Bureau for the Protection of Childhood at Monte Video, in the course of his address, mentioned that at the Congress at Santiago (Chili) in 1924 all the delegates signed the declaration.

The Exhibition.

In the afternoon the exhibition was visited officially by Mr. Haeberlin. The comprehensive exhibit of Great Britain with over 2000 items included several excellent health posters. The Swiss exhibit was particularly good; Pro Juventute, an organisation centring in Zurich, which possesses three travelling exhibitions, showed an excellent display, which included articles used in the Froebel and Montessori methods of teaching. This society organises work for children's leisure hours. The Union International de Secours aux Enfants, located at Geneva, set out the help given by 35 countries to the children of 38 other countries. The most striking feature of the French exhibit illustrated the work carried out by Mme. J. René Dubost in placing babies in families in Mainville and Milly, where they are visited regularly by English nurses and taken weekly to the local infant welfare centre also established by Mme. Dubost. Later the children are boarded out by the Assistance Publique in peasant families on farms. The most prominent Austrian exhibits illustrated the activities of the municipality of Vienna and the work of the Art School of Prof. Cizek, also of Vienna. The German exhibit, which was extremely well arranged, illustrated the work of the German Red Cross and the national equivalent of our "Save the Children Fund."

Sectional Meetings.

On Tuesday morning the sections met. The Medical Section dealt with the measures used in different countries to reduce infantile mortality before and after birth, tracing the problem back as far as the advocacy of the marriage of healthy parents. Dr. Rott (Berlin) spoke on prematurity; Prof. Pinard (Paris) referred to the evils of separating a child from its mother.

Infant Mortality.

Dr. A. K. Chalmers (Glasgow) held that we ought to consider whether the special decline of the infantile mortality-rate in our country was due to our efforts, or whether it were a biological phenomenon. He said that a decline had been recorded in all the countries of Western Europe, even in those where very little preventive work had been done, and that the mortality was increasing in some countries, such as Egypt, in spite of administrative efforts. The fall in the rate in the British Isles had occurred in the children of a generation which had profited by the important addition of foreign meat to their food-supply. He thought we had not done enough to interest and educate fathers. The need at present was to get mothers to appreciate the value of the medical supervision of children between 1 and 5 years of age. He had found the mothers in Glasgow unwilling to avail themselves of antenatal care until one mother profited; she became an ardent apostle, and after that there was no difficulty in filling the clinics. Mme. Vivier-Robert (Strasbourg) indicated the importance attached in Alsace-Lorraine to the work of the health visitor. The members of the audience were very much impressed by the close correlation of the fall in infantile mortality, with the dates of the introduction of various specific preventive measures. Dr. Bornstein (Berlin) and Dr. A. Koller (Lausanne) spoke on alcohol in this connexion; both considered alcoholic habits and the alcoholised constitution of parents responsible for a considerable part of infantile mortality.

Prof. Winifred Cullis (London) referred to the striking reduction in infantile mortality from syphilis brought about by the treatment of pregnant women in Scotland and London.

The Feeding of Children.

In the discussion on the feeding of children of all ages Dr. R. C. Jewesbury (St. Thomas's Hospital) expressed his belief that no artificial preparation could take the place of breast-milk. He referred to the possibility of re-establishing lactation after it had ceased for six to seven weeks, also to the absence of any organisation in England for supplying wet nurses. He would like a uniform system of feeding adopted in England. Prof. Taillens (Lausanne) also held that every effort to lessen infantile mortality must take breast-feeding as its fundamental principle. A valuable paper on the feeding of the pre-school child was read by Prof. Bernheim-Karrer (Zurich); he thought that digestive disturbances due to faulty feeding were increasing; he had found that over-feeding with milk caused constipation, and even anæmia if too little fruit and vegetables were given. Dr. E. Nobel (Vienna) thought that for the school child breakfast should be one of the principal meals and equal in nutritive value to the midday and evening meals; during the morning and afternoon there should be two light meals.

Prof. R. G. Freeman (New York) described clean milking on a farm which supplied New York and showed slides, one of which demonstrated how a cow was prevented from lying down between grooming and milking. He said that bovine tuberculosis was being rapidly eliminated in the United States. Prof. Caronia (Rome), in an interpolated paper, dealt with his recent work on the prophylaxis of measles and scarlet fever; the part of the paper that dealt with measles was discussed by Dr. E. Nobel.

Heliotherapy.

On Thursday morning during the discussion on heliotherapy, Dr. Knut Wejdling (Stockholm) emphasised the importance of giving cod-liver oil with the light treatment. Dr. A. Rollier (Leysin) showed a series of slides demonstrating the results of the work carried out at Leysin. Dr. P. F. Armand-Delille (Paris), in an interpolated paper on tuberculosis, written in collaboration with Dr. Lestoquoy, described the work of the Œuvre Grancher, which places the healthy children of tuberculous parents in families living in the country. Drs. Messerly (Lausanne), Chatin (Lyon), Mme. Vivier-Robert (Commissariat-General de la République, Strasbourg) described the work done in their areas. The paper of Dr. O. Bernhard (St. Moritz), the originator of the use of sunlight in surgery, should be read in full. Dr. C. W. Saleeby (London), in a model address, referred to the glass made in Birmingham for windows which contains no lead and no large atoms to prevent the passage of the ultra-violet rays.

Orthopædics.

The chief addresses on the prevention of crippling in children were given by Prof. Hans Spitzy (Vienna), Mr. R. C. Elmslie (St. Bartholomew's Hospital), and Dr. Murk Jansen (Leiden). Prof. Spitzy showed slides illustrating what to do and what not to do to prevent deformities of growth during the critical period of life until the baby has acquired the upright position. On the walls of the room were displayed some extraordinarily good original pictures in colours by Udo Weith, with suitable text, dealing with the prevention of crippling. Mr. Elmslie, whose contribution also evoked great applause, thought that medical inspection in London schools was responsible for the large reduction in the number of cases of scoliosis. He asked the representatives of other nations to publish an account of the organisation of the work for cripples in their countries, and mentioned that many of the British orthopædic surgeons who had worked under Sir Robert Jones during the war had become personal friends and were thus able to meet and discuss their various difficulties and new methods.

Dr. Murk Jansen was much concerned at the evil effects on the offspring of excessive smoking by the expectant father and mother. He considered that the tobacco habit had a marked effect on growing cells. Some of the most valuable of the papers of the congress dealt with the unification of the prenatal, neonatal, and later infantile mortality statistics of different countries. Dr. Rott (Berlin) explained the importance of the work of the subcommittee of the League of Nations, which had formulated a definition of stillbirth for international use; Dr. L. I. Dublin, the statistician of the Metropolitan Life Assurance Company, New York, pointed out that in the States 4 per cent. of the total births are stillbirths, and that their number is practically the same as the number of deaths which take place during the second to twelfth months of life. Yet very little statistical work was or could be done by any country at present. Dr. Marcel Ney (Berne) also read a valuable paper on this subject.

In the other sections the chief papers of medical interest were read by Dr. Th. Simon (France) and Mr. Cyril Burt (London) on the standardisation of the definition of mental deficiency and its different degrees, and by Dr. D. C. Kirkhope (Tottenham) on the education of public opinion in child welfare.

At the concluding meeting of the Congress a number of resolutions were passed summing up the recommendations made during the meetings of the sections.

Excursions.

A pleasant feature of the Congress were the informal receptions held by Prof. and Frau Pirquet. After a trip on the lake the Medical Section were charmingly entertained by the Genevese Medical Society and the other sections by Mme. Gustave Hentsch and Mr. Edmond Chenevière. During the Congress visits were paid to local institutions in Geneva, including le Rayon de Soleil at Frontenex, an adapted football stand and pavilion; one of the three open air schools; a *pouponnière* at Orange Canal; a home for unmarried mothers (La Retraite); the J. J. Rousseau Institute for research work in child study and experimental pedagogy; and the Cantonal Hospital with its maternity and isolation blocks. Unofficial visits were paid to see Mr. Spahlinger and his work, to Dr. Rollier at Leysin under the guidance of Dr. King Brown, and to the Institut d'Hygiène, where Mr. Maurice Valerien briefly indicated the chief sanitary features of the city and of the Canton of Geneva, and to Nestlé's milk factory at Verey.

On Saturday the Congress visited Leysin, the village which has grown up round Dr. Rollier's first clinic, a modest chalet since expanded into 33 establishments capable of dealing with 1000 adults and 300 children at a time. Although many know the work from the film shown in England, nothing but a visit to the village can enable anyone to envisage the place as a whole in the beauty and charm of its setting. It is evident that although the pioneer work carried out at Leysin by Dr. Rollier and his large staff has been and still is of great value, the organisation of the work of a similar kind in England to-day is equally good; the arrangements for the education of the child of school age while under treatment have, perhaps, been somewhat better organised owing largely to the work of the Board of Education; the after-care work in our country is also better. Possibly we have something still to provide in the way of arrangements for manual work for adults.

A visit was subsequently paid to Zurich under the guidance of Dr. Pfeiffer of the Pro Juventute Foundation. An unpretentious but well-run epileptic institution was inspected, under the charge of Dr. A. Ulrich, who considered sedobrol and a salt-free diet of great value. At the Orthopædic Hospital, Anstalt Balgrist, an address was given by Dr. Richard Scherb, and the good following-up system was described. At the Cantonal Institution for Blind and Deaf and Dumb Children the two types were kept entirely apart. Oral teaching only was carried on for the deaf and dumb; if a child could not be taught by this method it was not retained in the institution. The bedrooms for the children were good enough for a first-class hotel.

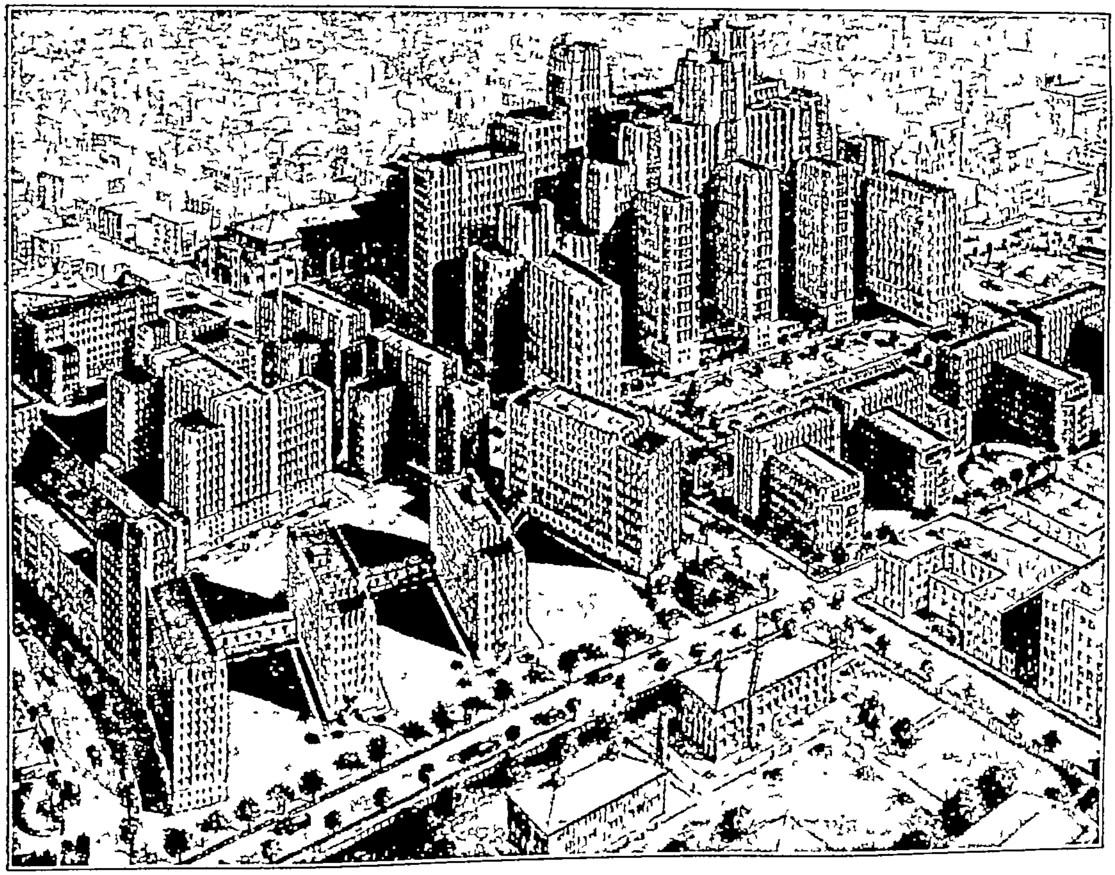
In the afternoon a pleasant home for unmarried mothers was visited with 10 beds and 30 cots; the mothers were confined here and allowed to remain in for another six weeks, the babies might be left in for two years or even more; later to the Children's Hospital and Polyclinic, of which Prof. E. Feer is the director. Here the most interesting feature were the glass cubicles in the observation block used for definite and suspected cases of infectious diseases. The visitors were informed that congenital syphilis had been so rooted out of Zurich that it was difficult to find clinical material for the students.

The conference as a whole was remarkably successful; it not only brought together fellow workers from many countries, but also provided matter for subsequent study by the technical experts.

THE "MEDICAL CENTRE" OF NEW YORK.

THE erection of the Columbia Presbyterian Medical Centre has now commenced and it is hoped to make of New York one of the world's greatest centres of medical teaching and research. The site occupies an area of 20 acres overlooking the Hudson River. The first building will be the new home of the Presbyterian Hospital and of the College of Physicians and Surgeons of Columbia University. This building will contain some 23,000,000 cubic feet, or one and a half times the space in the Woolworth Building in New York, the tallest building in the world at present. It is hoped ultimately to group together many medical institutions, covering many fields of treatment, education, and research which, though independent, will nevertheless coördinate the service of the sick and further the cause of health. Provision will be made for 1400 beds. The institutions already included in the plan, in addition to the two mentioned above, are the State Psychiatric Institute and Hospital, the Neurological Institute, the Babies Hospital, the Sloane Hospital for Women, the Vanderbilt Clinic, and the Presbyterian Hospital School for Nursing. All these are established institutions carrying on their work in old buildings in other parts of New York, and it is expected that their removal to new and larger premises at the medical centre will be effected with little or no interruption to their routine. Other institutions which it is hoped to include in the centre are ear, eye, nose, throat, and skin hospitals, a dental school, training schools for public health and social workers, a convalescent home, as well as dormitories for students and housing for the staff and personnel.

The Presbyterian Hospital Building will have 17 stories; the first floor and mezzanine will be for administrative uses and the next 13 will be ward floors. Above them will come an operating floor and mezzanine, while on the top floor will be an open-air gymnasium, loggias, and a recreation roof. Each ward floor will be as nearly as possible a hospital in itself, with 64 beds, divided into single and small wards. Attached to them will be a laboratory, treatment rooms, service rooms, three solaria, and a reception and lecture room on each floor. Each floor will have its own permanent nursing staff. In this way the patient will have all the advantages attaching to a small institution while at the same time commanding the resources of the centre as a whole. The private patients' pavilion will have 125 rooms, and there will be accommodation for relatives and friends who wish to live near the patients for a short period.



The Columbia Presbyterian Medical Centre as it will appear when completed. The new Presbyterian Hospital, now under construction, is the nearer half of the large central unit.

The medical school of Columbia University will have a building of the same height as the hospital building and connected with it on all the floors by an axis in which will be offices for the doctors and rooms for equipment to be used by both the school and the hospital. Included in the plan is an operating amphitheatre to serve the group and afford a clinical meeting-place for medical congresses. A unit corresponding to the medical section is reserved for the future development of the Vanderbilt Clinic, while the site for the Babies Hospital will be large enough to accommodate some 160 beds, thus enabling it to extend its work to include older children as well as infants. The Presbyterian Hospital of Nursing will have a building for 400 nurses. The eighth floor of the General Hospital Building will be devoted to the Squier Urological Clinic and will represent a self-contained unit devoted to bladder and kidney surgery, equipped with the most modern methods of diagnosis, with accommodation for 61 patients. Special floors will be allotted to the Sloane Maternity Hospital, which will have an obstetrical ward capacity of about 125 beds; while the Neurological Institute will need space for 200 beds, the number allocated to the State Psychiatric Institute and Hospital, now located on Ward's Island. There is distinct need for a recovery home which, it is hoped, will be erected on Riverside Drive, where the patient will have the advantage of being easily accessible to those under whose observation he should remain while recuperating.

Special attention will be devoted to the housing of the students and personnel. The keynote of the medical centre will be cooperation. It will be not so much a single organisation as a community in which everyone is concerned with the same general problem of restoring the patients to health and keeping them well afterwards. Each institution will retain its independence and will have its own trustees or managers, but they will all work together through the joint administrative board, composed of representative physicians and laymen.

While the cost of the buildings now in progress is estimated at $10,000,000, the final cost of the centre can only be vaguely guessed at at present. It certainly will run into many millions sterling. In the same way, it is difficult to estimate the time it will take to evolve the project to its fullest possibilities. The present belief is that it will need a generation, but maybe some public-spirited millionaires will come forward and provide the funds to carry the scheme to completion in ten or a dozen years from now.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Restriction of Hospital Beds Under Government Control.

FOLLOWING the stringent measures of economy, to which our budget is forced by the control of the League of Nations, a number of Viennese hospitals are to be closed down because the beds in these institutions are not in full-time occupation. Owing to the new hospitals erected on the outskirts of the city within the last 15 years, and to the numerous well-equipped new hospitals in the smaller provincial towns, the sick and the ailing do not flock to Vienna as they used to do. The diminution of the number of inhabitants of our country—now 6½ millions against 50 millions formerly—has also had its effect. The Government has found it more feasible to distribute the patients all over the country, thus keeping the minor hospitals in the provinces fairly busy. Not only has this scheme advantages from the point of view of economy, most of these hospitals being maintained by the local authorities, but it also promotes the general professional standing of the country doctors. Three hospitals have thus already been closed in Vienna, and the fourth—the Poliklinik, well known to every student of medicine in Vienna—has only escaped this fate through reorganisation; it is now rapidly becoming a hospital for the middle-class citizen with limited means. Its out-patient department, however, is working as usual. In order to understand the situation it must be added that in this country until 30 years ago all hospitals were Government institutes, with the exception of a couple or so of private hospitals, and one municipal hospital in Vienna. The system of hospital support by voluntary contributions is not known here. Local hospitals, indeed, were erected not very long ago in smaller towns by the municipalities and in Vienna by private corporations, but they soon had to fall back on Government support, especially in the years 1914–24. Now conditions have changed. What we really do want is not so much an increase of general hospital beds, but tuberculosis beds. Even here, however, our expenditure is curtailed by the urgent order of the "League" for economy.

Is the Human Saliva Poisonous?

An incident occurred recently in a public bath which has caused comment in medical circles. The facts are as follows: A girl of 15 was playfully bitten by a young man on the thigh whilst the two were enjoying themselves in one of our public sunbaths. The girl applied for medical help, stating that the bite had been caused by a dog, and was promptly sent to the hydrophobia department of the institution for experimental pathology. There she underwent a course of anti-rabic injections. She soon developed marked weakness, hypersensibility of the skin, pyrexia, and gradually symptoms of paralysis of several limbs appeared. After about a dozen injections the girl died. Rumours soon spread that she died in consequence of the injections, especially when her girl friends volunteered the information that the bite was inflicted not by a dog but by a young man. Police investigations were at once instituted and a post-mortem was obtained, in which it became clear that the girl had died from acute poliomyelitis, the fatal illness having no connexion either with the bite or the injections. But in the course of the public discussion, Dr. Kraus published an essay in which he set forth present knowledge regarding the toxicity of the human saliva. Many authors in the past, including Galen and Pliny the Younger, have pointed out that this fluid has a special activity. In comparatively modern times, about 90 years ago, Eberle reported from personal experiment that saliva had toxic effects, this quality depending on emotional conditions. A series of investigations were conducted by Pasteur in his laboratory, showing that over 32 different strains of pathological micro-organisms have been isolated from human saliva, some with distinct virulent effects, besides about 20 strains of non-virulent type. Dentists know very well that the mouth is a focus of infection. The assumption that the girl died from the human bite could not therefore be repudiated off-hand. But investigation proved that by a coincidence death had occurred from an infectious disease and was quite unconnected with the playful assault.

Two Distinguished Medical Contemporaries.

One of the most eminent of the Vienna medical teachers, Prof. N. Ortner, director of the second medical clinic in our city, recently celebrated his sixtieth birthday. A native of the city of Linz, he studied in Vienna in the clinics of Bamberger and Neusser. As assistant to the latter he found excellent opportunities for the study of numerous pathological conditions. His chief attention centred at that time in the conditions of the liver and gall-bladder, and his books on "Cholelithiasis" and "Infection of the Bile-ducts" won for him the gold medal of the Vienna University. Between 1895 and 1899 he published a series of papers on diseases of the vagus, paralysis of the recurrens, and on adventitious murmurs in peritonitis and pseudo-pericarditis, which showed a brilliant gift of keen observation. He thereafter published a series of lectures on special therapy of internal diseases, a concise and easily intelligible contribution to modern medicine. He was called to Innsbruck as clinical teacher (1907–11), but in 1911 he was recalled to Vienna and since that time has acted as a prominent member of the teaching staff of the university. Ortner is held in high esteem by his colleagues, as the recent "festschrift," published by the *Wiener medicinische Wochenschrift* showed.—Another birthday jubilee has also been celebrated recently. The well-known ophthalmologist, Dr. S. Klein, completed his eightieth year in full health. He was one of the first pupils of Jäger, and is the only man here who still examines the fundus with Jäger's ophthalmoscope, a method of excellent value, but hardly known to the younger generation. Klein's merits are on the diagnostic and therapeutic side of his science, and his skill as an operator is still a joy to those privileged to watch him.

SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Medical Congress at Maritzburg.

THE twentieth South African Medical Congress was opened in the Town Hall, Maritzburg, Natal, on July 6th, by Sir John Dove-Wilson, the Natal Judge President and President of the Council of Natal University College. There were 120 delegates present from all parts of the Union of South Africa and Rhodesia. Sir F. Spencer Lister, representing the South African Committee of the British Medical Association, inducted Dr. Dugald Campbell Watt, J.P., one of the oldest practitioners in Maritzburg, to the chair as President of the South African Medical Congress. Sir John Dove-Wilson, in his address, said his endeavour was to emphasise the extent to which the two professions of medicine and law are associated in a common task, and to acknowledge the great debt which the law owes to medicine for its loyal assistance and coöperation in the great work of doing justice between man and man. He dealt with the difficult problem of professional secrecy, and remarked that patients had no right to expect, or doctors to demand, that knowledge gained in their professional capacity should not be divulged by doctors in a court of law when it was relative to the matters at issue.

The President said that it was 20 years since a medical congress had been held in Maritzburg, and many changes had taken place. He recalled his predecessor in the chair in that city 20 years ago, Colonel James Hyslop, D.S.O., V.D., M.D., a man honoured in his day and generation. As against the sad and inevitable losses that the efflux of time had caused, they had seen in those passing years the advent of many young, energetic, and well-qualified colleagues, both eager and able to carry on the ideals and duties of their profession.

The President's address dealt mainly with the necessity for a spirit of unity, and outlined the history of medical associations in general and the S.A.M.A in particular. He said that the science and art of medicine in all its branches had become so intricate, extensive, and profound that no one human brain, however brilliant, could hope to reach the highest standard of efficiency in all. The practitioner was, therefore, compelled to collaborate with others who had; after qualifying, made one subject or another their special study. Strength was much required for the vigorous prosecution of their work in all its branches—from research to clinical—and this could only be effectively utilised and developed by uniting the whole of the necessary forces in the State, both lay and professional. All had one object in view: the greater alleviation of suffering, the abolition of the causes of disease, and the propagation of a sane, healthy, and virile population. It was the duty of the State to afford them its moral and financial support.

On the first evening of the Congress a public lecture was given in the Town Hall, Maritzburg, by Dr. Shadick Higgins, M.O.H., Cape Town, recently medical officer of health for St. Pancras. His subject was Public Health in Relation to Social Welfare. Ten papers were read at the Section of Medicine and Mental Hygiene, under the presidency of Dr. E. P. Baumann. The meeting opened with a paper by Dr. R. L. Girdwood on Focal Infection. The Surgical Section met under the presidency of Dr. A. McKenzie to discuss the Treatment of Carcinoma of the Breast, the subject being introduced by Mr. H. A. Moffat. The Public Health Section discussed the milk-supply and had two subsections for M.O.H.'s and school M.O.'s respectively. The causation and prevention of fœtal death was discussed at the Obstetrical Section under the presidency of Dr. A. Simpson Wells, and a special discussion on the work of the laboratory in relation to the practice of medicine was opened by Sir F. Spencer Lister.

Obituaries.

The late Dr. J. A. Clements had filled the post of Government district surgeon for the Umsinga district of Natal, and was an extremely popular and honoured officer. His death followed an operation for internal ulcer.—The late Dr. Wynn Westcott had become a resident of South Africa after his retirement from the coronership in London. He had attained much distinction in Blue Masonry and had been a Master of Lodge Quatuor Coronati, the membership of which is restricted to Masons noted for original research and literary work. He was also a student of the Kabalistic philosophy, Hermetic writings, and the work of the alchymists and Rosicrucians, of which latter he held the office of Supreme Magus.

A Central Leprosy Hospital.

The Union Leprosy Commission concluded its deliberations at Cape Town on June 24th, and will not meet again this year. According to *Die Burger*, the Commission recommends doing away with all the several smaller isolation places and having one central leprosy hospital in Pretoria, as being the most suitable position. The idea is to make this hospital a modern model institution, and the Commission, it is stated, has worked out a scheme which will save the Union Department of Public Health about £20,000 a year. Some members of the Commission were in favour of having a medical expert specially brought to South Africa in order to advise the Government on the building and fitting out of the proposed hospital.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Irish Free State and the Medical Register.

THE controversy on the question of medical registration in the Irish Free State is still carried on in the Irish press, but it has shown a milder tendency in the past ten days. This change of atmosphere is due in large measure to the conciliatory attitude taken by Mr. Cosgrave, the President of the Irish Free State. In reply to a memorandum sent to him by the President and Fellows of the Royal College of Physicians, he invited the College to send a deputation to discuss the matter with him. The deputation met him on Sept. 3rd, and a frank discussion was held on the present situation. Mr. Cosgrave was firm on the point that the Government was determined to establish a medical register for the Irish Free State, and, if forced, was prepared to go to the country and fight the matter at the meetings. The Government had not yet framed a Bill, and he invited the coöperation of the profession in its drafting. As soon as the Bill was framed it was the intention of the Government to approach the English Government with the view of obtaining some sort of reciprocity between the two countries; and he believed that he would obtain such a measure of reciprocity as would not endanger the status of persons seeking Irish medical qualifications. The deputation urged that, if the Government were determined to set up a medical council and register in the Free State, the existing conditions should be allowed to continue until such time as that had been accomplished. Mr. Cosgrave, while remaining sympathetic towards this view, pointed out that any such continuation of the existing conditions would be granted only on the condition that prolongation was not used for the purpose of delaying the establishment of an Irish register.

Mr. Cosgrave has invited the members of the Consultative Committee, consisting of representatives of the educational bodies and of the medical profession, to meet him in conference on Sept. 9th. In the meantime, the meeting of protest, to be held on Sept. 8th, will have contented itself with a recognition of Mr. Cosgrave's conciliatory attitude.

Sept. 7th.

INDIA.

(FROM OUR OWN CORRESPONDENT.)

A General Medical Council for India.

IT is interesting to learn that a private member proposes to introduce, in the coming session of the Indian Legislative Assembly, a Bill for the formation of a Council of Medical Education in India. The idea is to create a body on the lines of the General Medical Council of the United Kingdom for controlling medical education under the direction of the medical profession. As one of the objects of the measure will be to establish a qualification in the indigenous methods of treatment of disease, it is not surprising that disapproval has been warmly expressed at a meeting of medical men held in Bombay.

The Committee appointed by the United Provinces Government to advise them regarding the best means to be adopted for improving the Ayurvedic and Unani systems has commenced its labours, but it will be some time before it presents its report.

The Supply of Medical Students.

At the Medical College, Calcutta, 120 vacancies were announced for the last winter session, and there were 1000 applications. The Government of Bengal control the college, and were therefore able to issue specific orders as to the qualifications of applicants. The most noteworthy of these were: (1) that a few places were reserved for men who had taken the B.Sc. degree; (2) that half were reserved for candidates who had passed high up in the intermediate science examination; (3) that four places were reserved for the sons of distinguished medical men; and (4) that only five places were reserved for women students.

Broadcasting Epidemiological Information.

It was decided at a conference attended by delegates from 12 Far Eastern administrations that the first appearance in any part of Asia or Australia of cholera, plague, small-pox, yellow fever, or the unusual prevalence of any other infectious disease, should be immediately reported to the Far Eastern Epidemiological Bureau, and that a weekly bulletin should be despatched recording: (1) The mortality from these diseases; (2) the existence of plague infection among rats; and (3) notes of unusual epidemics. The information collected by telegraph from the various Governments is broadcasted by the Government of French Indo-China from their wireless station at Saigon, and in India this information is received at Simla by the Public Health Commissioner with the Government, and then distributed to the health officers of the large Indian ports, who have thus, each Saturday morning, detailed information regarding the health of the major ports of the Far East up to the midnight of the previous Saturday.

Extended Distribution of Anti-Rabic Vaccine.

The Pasteur Institute at Kasauli is now issuing vaccines on a large scale to various centres for anti-rabic treatment. Prior to Jan. 1st of the present year, the only regular issue of vaccine was to a railway centre at Allahabad, but recently a centre was opened by the Punjab Government at Lahore, one at Rawalpindi for soldiers, and another at Rajkote, in Kathiawar, and these are likely to be followed by others in various parts of India. The Behar and Orissa Governments have decided, moreover, to open a centre and make their own vaccine. These developments enable patients to be treated in their own districts.

Child Welfare Work in Madras.

The Government in reviewing the report on child welfare work for the quarter ending March 31st, 1925, state that only three district boards, 23 taluk boards, and 84 municipalities have sent in reports of their work. There are only 45 centres in the Presidency for a population of over 43 millions. The districts of Cuddapah, Kurnool, Guntur, Nellore, and Malabar do not possess a single child welfare centre. On the other hand, there are eight centres working in the Chittoor district, and among the remaining districts, three—the Nilgiris, Vizagapatam, and Chingleput—have four centres each, two others have three centres each, six have two each, while the rest have one centre each. The municipalities of Chingleput, Madura, Vellore, Tanjore, and Ootacamund have each of them two centres, the two at Chingleput having been organised and maintained by the Red Cross Society. Only seven new centres were opened in the Presidency in the year under review, in spite of the Government's special appeal in the last year's review. Thirteen local bodies have organised committees for intensive child welfare propaganda and the inauguration of new centres wherever feasible. To facilitate the opening of more child welfare centres and their efficient working the Government have decided, as an experimental measure, to train four women as health visitors with a view to their subsequent employment by local bodies.

A successful "Baby Week" was recently organised in Poona.

Training and Employment of Qualified Midwives.

Only 17 municipalities and eight taluk boards are so far known to have employed qualified midwives in their service. Of these, four were appointed during the year under review by the municipal councils of Villupuram and Cuddalore, and the taluk boards of Perambalur and Koilkuntla. The appeal made by the Director of Public Health to the local bodies to take steps for the training of midwives did not meet with sufficient response. The supervision of the work of trained "dhais" and the improvement brought about by training do not seem to have been adequate.

Medical Inspection of School-children in Madras.

The system of inspection of pupils in recognised secondary schools sanctioned in 1920 is now to be put into force. The inspection will be confined for the present to recognised secondary schools for boys, school departments of colleges and training schools, and will be carried out annually by local practitioners selected by the local boards of management or the Director of Public Instruction in consultation with the Surgeon-General. The aim will be to ascertain the general physical condition of the pupil, the treatment of those suffering from disease being left to the parents. The management of the school undertakes to maintain the records and submit the required returns.

Meagre Hospital Facilities in Bombay.

The Government of Bombay has addressed the municipality on the subject of the inadequate hospital accommodation provided in Bombay, in comparison with its population and importance. The number of beds available for the treatment of general diseases is only 526, or approximately 1 bed for every 2000 of the population. On making a comparison with the other leading cities of India, it has been found that the number of beds per 1000 of the population is as follows: Lahore, 7·2; Madras, 3·4; Calcutta, 2·6; Bombay, 0·5. The Government call for a conference to discuss the subject of medical relief in the great city which has been aptly called "The Gateway of India."

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics of six counties for 1924:—

Name of county.	Mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Surrey	742,900	14·9	10·6	0·80	1·46	2·0	—	52	3·6
Wiltshire	305,100	17·1	11·4	0·83	—	—	—	55	4·0
Northamptonshire	316,200	16·2	11·6	0·91	1·31	1·0	—	52	3·4
Warwickshire ..	358,300	18·8	11·0	0·89	1·25	1·9	—	60	4·3
Leicestershire ..	273,100	18·8	11·7	1·01	1·29	2·2	—	60	2·7
Fife (landward area)	108,161	24·0	12·2	0·83	1·06	3·1	—	84	3·1

Surrey.

Dr. Joseph Cates reports that the infant mortality and general death-rate are slightly higher than in 1923, and that influenza and its respiratory complications were among the causes of this increased death-rate. The county council now has a comprehensive and compact scheme for all branches of home visitation which has been evolved so as to obviate overlapping. The county is divided into 12 areas. In each area there is an assistant medical officer, who carries out school medical inspection and treatment, maternity and child welfare and dispensary duties. Three or four health visitors, who are fully trained nurses and hold the certificate of the C.M.B. and the health visitors' certificate of the Royal Sanitary Institute, are allocated to each area. These health visitors carry out antenatal and birth visitation, follow up defects discovered in the scholars of the elementary and secondary schools, inquire into tuberculosis, supervise the mentally and physically defective, and visit the blind.

Surrey now has an organised scheme for the discovery and treatment of crippling defects. Children are referred to the assistant medical officers by the health visitors, teachers, school attendance officers, and voluntary workers, and after examination are sent to the orthopædic centres included in the scheme. Children of school age, who reach the centres on the advice of medical practitioners and other agencies, are seen by the assistant medical officers before the committee accepts liability for treatment. The approved orthopædic centres are the Guildford County Hospital, the Croydon General Hospital, the Nelson Hospital at Raynes Park, and the aid-posts of the Red Cross Society at Kingston and Woking. At each centre there is in attendance an orthopædic specialist and nurses trained in massage, electrical treatment, and plaster work. Minor operations are carried out at the centres; major operations in one of the hospitals mentioned or a London hospital. For certain of the patients prolonged in-patient treatment is necessary, and 50 beds at the homes of the Waifs and Strays Society at Pyrford have been secured for the purpose. These homes are recognised by the Board of Education and are well equipped for the operative treatment and education of cripples. The county council pay 3s. per attendance at the centres for cases referred by their assistant medical officers and £104 a year for each occupied bed at Pyrford.

Dr. Cates refers to the complaints, which are made from time to time by the Surrey local sanitary authorities, as to the dumping of refuse by certain of the metropolitan borough councils, and is emphatic that the time has arrived when urban communities should destroy their refuse in a properly constructed destructor. During the present year a survey will be made of the methods adopted throughout the county for the disposal of refuse. A report on isolation hospital accommodation in the county indicates the need for some reorganisation. For example, the Frimley Urban District Council's hospital at Mytchett is quite unsuitable, and diphtheria cases from this district are already sent to the Farnham Hospital. Dr. Cates considers that the Frimley hospital should be closed and all cases of infectious disease sent to the Farnham or some other hospital. Again, at Redhill are the well-constructed hospital of Reigate borough and the antiquated, unsatisfactory hospital of Reigate district, whereas the former building would serve both areas. A third recommendation is that the Epsom Urban District Council should close their hospital and arrange for their patients to be admitted to the Joint Hospital at Cuddington. The report for 1922 contained a complete survey of the Hogsmill; that for 1923 a survey of the Wandle; and the present report contains a survey of the Beverley Brook. The condition of the Beverley Brook, says Dr. Cates, is not so serious as that of the River Wandle, but furnishes additional evidence that the county council needs supplementary powers to enable them to deal satisfactorily with the condition of the rivers in the county.

Wiltshire.

Dr. Claude E. Tangye reports an increase in the prevalence of encephalitis lethargica, there being 12 cases notified as against three in 1923. Four of the cases ended fatally and most of the survivors suffered damage to the nervous system. Five children of school age survived the disease with impaired mentality and a sixth with facial paralysis. Other cases of this disease have occurred which were not notified at the acute stage, but only diagnosed by the after-effects. The orthopædic clinics which have been started at Devizes, Trowbridge, Corsham, and Swindon in connexion with the Children's Orthopædic Hospital at Bath, have been of great value to the tuberculosis scheme. Dr. Tangye points out that the notification of tuberculosis is still incomplete and that about one-fifth of the deaths from tuberculosis in 1924 were unnotified cases. An arrangement has been made with Swindon whereby midwives notify all cases of discharging eyes, however slight, to the borough medical officer of health. Under this scheme 13 notifications were received by Dr. D. Brewer, the Swindon M.O.H., and the cases were subsequently treated at the borough child welfare clinic with most satisfactory results. The health visitors of the county council supervise boarded-out children for most, but not all, of the boards of guardians in the county. In consequence of the relatively high rate of maternal mortality in the county, the district medical officers of health were asked to furnish details of all deaths from complications of childbirth in return for a small fee. A number of such reports have been received, but it is too early to judge of their value. There are now six maternity and child welfare centres in the county. The centre at Trowbridge is the only one administered directly by the county council, the others being under voluntary committees. Antenatal work has been begun at the Trowbridge centre, and the employment of practitioners of special experience in this work is a question which is receiving careful consideration.

The report on the sewage works of the county shows that there is considerable pollution of the rivers by a large number of unsatisfactory effluents. Only one licence has been issued by the county council under the Milk Designations Order—namely, for Grade A milk. The shortage of houses in Wiltshire is still acute and very little is being done in the matter of the inspection and repair of insanitary houses. Dr. Tangye reports that the provision, by which the local sanitary authority can carry out repairing work in the default of the owner and charge the owner with the cost, is practically never used. It is surprising to learn that there are four rural districts which have no building by-laws. Of these, says, Dr. Tangye, "the Bradford-on-Avon Rural District is conspicuous for the activity of building operations quite uncontrolled by the local sanitary authority."

Northamptonshire.

Dr. Charles E. Paget notes the passing of the Thames Conservancy Act, 1924, as one of the important events of the year. By this Act the jurisdiction of the Thames conservators has been extended to six additional counties—viz., Northamptonshire, Warwickshire, Worcestershire, East and West Sussex, and Bedfordshire. The effect of the Act is to bring all sources of sewage pollution of the River Cherwell and its tributaries within the rural districts of Brackley, Daventry, and Middleton Cheney under the surveillance of the conservators. When the Bill came before Parliament there were three serious pollutions of the Cherwell. In respect of two of these action had already been taken, but the Brackley R.D. Council had refused to carry out a scheme for Kings-Sutton on the grounds of expense. Dr. Paget points out that the standard of purity required by the Thames Conservancy is much higher than that adopted by any authority enforcing the Rivers Pollution Act. Presumably the Brackley R.D. Council will have to come into line. Dr. Paget reports an increase in the prevalence of encephalitis lethargica. There were 19 notifications in 1924, as compared with 6 in 1923; 9 of the cases ended fatally; 7 of the 9 deaths occurred at or over the age of 45.

The inspection of dairy cows in the county during the year was interfered with by outbreaks of foot-and-mouth disease. To Dr. Paget's regret, veterinary inspection is not in operation in all parts of the county. There are two joint committees in the county for veterinary inspection and the results judged by success in finding cows with tuberculous udders are a curious contrast. Thus the veterinary inspector of the Kettering Joint Committee found six cases of tuberculous udders among 3808 cows, while the veterinary inspector of the Wellingborough Joint Committee found 10 tuberculous udders among 2070 cows. The county analyst, Mr. E. W. Voelker, reports that nearly 10 per cent. of the 371 milk samples were adulterated, 26 being deficient in fat and 10 being watered. The proportion of butter samples containing boric acid preservatives was much less than in 1923. One reads with interest that two samples sold as "ginger brandy" were non-alcoholic syrups flavoured with ginger, while a beverage with the innocent name of "cowslip wine" contained 20 per cent. proof spirit.

Warwickshire.

Dr. A. Hamilton Wood reports a considerable amount of progress in the matter of prevention of river pollution. The activities of the Upper Tame Basin Joint Committee have stimulated the authorities whose effluents were polluting the Tame before it reached Warwickshire. The Birmingham Tame and Rea District Drainage Board have introduced many improvements including bio-aeration plants, and a great improvement is expected in the quality of the effluent of 30,000,000 gallons per day discharged into the Tame below Water Orton. The condition of the River Cole is also improved. Important reconstructions have been carried out at the sewage works of both Hinckley and Nuneaton, which will improve the condition of the River Anker. The Avon is still polluted by sewage from the city of Coventry, but it is expected that an improvement will shortly result from the installation of the bio-aeration plant which is now in progress at the city sewage works. The effluents from the Warwick sewage farms and the Leamington sewage works are still unsatisfactory.

The county analyst, Mr. Rigby, reports that the average composition of the milk samples analysed during the year showed 8·75 per cent. of non-fatty solids and 3·88 per cent. of fat. For the first and fourth quarters of the year the average was about 8·74 per cent. of non-fatty solids and 4·02 of fat. For the two middle quarters of the year the non-fatty solids averaged about 8·76 and the fat 3·73. The fat was thus 0·3 per cent. higher during the winter quarters. The record of the V.D. clinics shows an increase in new cases dealt with from 170 in 1923 to 204 in 1924. The patients who ceased to attend without completing treatment numbered 110, while only 40 were discharged after the completion of treatment. Dr. Wood, referring to the statement of the Ministry that no Exchequer grants are available towards the cost of the training of midwives, points out that local expenditure either from voluntary or rate-aided sources must be increased if the efficiency of the county midwifery service is to be maintained.

In view of the high maternal mortality from childbirth provision has been made for complicated midwifery cases at several hospitals and at the county maternity homes at Warwick and Rugby. The Warwick home admitted six antenatal cases and the Rugby home 12 antenatal cases during the year. Only 144 new cases attended the antenatal clinics, while the number of births in the county was 6722. Both of the county homes have been recognised by the Ministry as training institutions for midwives. There were 34 notifications of ophthalmia neonatorum with no cases of impaired vision. This result is attributed to the routine use of a colloidal silver preparation by the midwives introduced in 1910 and perfected in 1920. The following are the cases of blindness in infants from ophthalmia neonatorum during the last nine years:—

Year.	Notifications of ophthalmia.	Blindness.		Year	Notifications of ophthalmia.	Blindness.	
		Both eyes.	One eye.			Both eyes.	One eye.
1916	66	1	1	1921	36	0	0
1917	60	2	0	1922	59	0	0
1918	46	1	1	1923	40	0	0
1919	52	1	1	1924	34	0	0
1920	56	0	1				

Leicestershire.

Dr. T. Robinson reports an effort towards the production of cleaner milk in the county. The county laboratory is to be extended and its staff increased in order to deal with milk samples sent by the district councils. Both the district councils and the vendors will be informed of the result of the examination. A clean milk competition was held during the year, for which 20 farmers entered. For the competition six samples were sent by the competitor and one surprise sample was taken. A steady improvement was noticed in the samples as the competition progressed. Of the 20 competitors eight produced Grade A milk in each of the seven specimens, while only one competitor failed to produce Grade A milk in any of the seven samples examined. The Ministry have issued four licences for Certified milk and one for Grade A (tuberculin tested), while the county council have issued Grade A licences to three producers. Small-pox was introduced into the county in December, 1923. There were 98 cases reported during 1924. The disease was of a mild type and caused no deaths.

Fife.

Dr. G. Pratt Yule, in referring to the fact that the Board of Health has issued an Order making infective jaundice compulsorily notifiable, states that this disease appears to be associated with a similar condition in rats and that it has occurred among miners in the county in the past, but would appear to have been limited to pits in the Lochgelly-Cowdenbeath area. During 1924 seven lupus patients were sent to Edinburgh to receive treatment at Sir Norman Walker's arc-light clinic at the infirmary. Dr. Yule and Dr. McGillivray (the tuberculosis officer) were much impressed with the results obtained at this clinic. They saw one case, who had been attending the infirmary for 40 years trying all kinds of treatment without benefit, and whose lupus was practically healed after four months of the light treatment. They recommended that a similar clinic be established at the county sanatorium at Glen Lomond. Dr. W. P. S. Johnson, the medical officer of the Dunfermline V.D. centre, reports that, as compared with 1923, there is an increase in the percentage of gonorrhœa cases and a decrease of syphilis cases. The percentage of cases which cease to attend before the completion of treatment was 13·8, which compares very favourably with the experiences of other centres. Dr. Johnson points out that the clinic in Market-street is unfortunately situated; for one thing, it is at a distance from the hospital where the in-patient treatment is carried out, but the principal objection is that the position is so exposed that prospective patients are deterred from attending. Housing conditions are still difficult, and the need is particularly urgent in the mining districts of Kirkcaldy and Dunfermline. No applications have been made for licences to sell graded milk.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 29TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 37; scarlet fever, 1302; diphtheria, 787; enteric fever, 81; pneumonia, 449; puerperal fever, 41; cerebro-spinal fever, 6; acute poliomyelitis, 12; acute polio-encephalitis, 2; encephalitis lethargica, 31; continued fever, 1; dysentery, 8; ophthalmia neonatorum, 109. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there was 1 death from enteric fever, 20 from measles, 5 from scarlet fever, 40 from whooping-cough, 12 from influenza, and 27 from diphtheria. There were 218 deaths of children under 2 years from diarrhœa and enteritis, as compared with 177, 186, 168, 101, and 64 in the preceding weeks. In London itself there were 10 deaths from diphtheria, 5 from whooping-cough, and 1 from influenza.

"Audi alteram partem."

THE INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—I was delighted this morning to read the leading article in THE LANCET on the Indian Medical Service. It was most refreshing after the orgy of pessimistic representations that have appeared in other papers. The article is, I believe, an accurate statement of the present position of the I.M.S., and taken with what appeared in the Students' Number last week should be very helpful to young medical men wishing to know the exact state of things.

I was very glad also to read your eulogy of Lord Sydenham's speech. The fundamental point is that the I.M.S. is not to be abrogated. I am inclined to think that once the home schools' embargo is raised there will be a rapidly increasing number of candidates for the I.M.S. There will be few home candidates for the 50 per cent. appointments of the civil or rather provincial medical services; the Lee Commission recommended that the shortage of these 50 per cent. was to be made up by additional transfers (apart from the War Reserve of 122) from the R.A.M.C. (India). If this is given effect to in the I.M.S., we shall go near to a restoration of the status quo ante. *Nous verrons!*

I am, Sir, yours faithfully,
P. HEHIR.

Westward Ho! Devon, Sept. 4th, 1925.

*** If the recommendations of the Lee Commission are applied in their entirety to the Indian Medical Service it follows, as we set out in the Students' Number of THE LANCET, that no attempt will be made to perpetuate that Service as at present constituted. Happily, the Government of India and the Secretary of State for India are in agreement that the Indian Medical Service must be maintained. Lord Birkenhead has still to communicate his final decisions, but there is nothing in the existing situation to belie optimism.—ED. L.

ADENOIDS AMONG SCHOOL-CHILDREN.

To the Editor of THE LANCET.

SIR,—In reference to the annotation upon this subject in your issue of August 22nd (p. 391), it may be of interest to your readers to be reminded of an investigation into the occurrence of adenoids in three of the London County Council elementary schools, the results of which I published 15 years ago.[1] The investigation dealt with 2315 children and was made during the winter of 1907–08. Without going into details, which can be seen in the reference given, the conclusions to be drawn were as follows:—

1. That on the average about 37 per cent. of the children in elementary schools have adenoids, and between 72 and 76 per cent. have enlarged tonsils as well.

2. That on the average 31·2 per cent. of adenoid cases are mouth-breathers, complete or partial, and that hypertrophy of the faucial tonsils may give rise to mouth-breathing in the absence of adenoids.

3. That sex appears to have no influence upon the incidence of adenoids.

4. That adenoids are most common about the age of 8 and are next most frequent at about 12.

5. That true aprosexia is often confused with apparent dullness due to defective hearing, and that true aprosexia occurs only in about 4·7 per cent. of adenoid cases, is more frequent in girls, and, when present, is associated with a marked degree of adenoids.

6. The so-called adenoid facies is uncommon, save in association with a marked degree of adenoids.

7. That the association of an abnormally high palate with adenoids is rather due to peculiarities of cranial formation than to extra-uterine influences of nasal stenosis, and that, if there is any relation between a high narrow palate and adenoids, it is possible that the palate shape is rather the cause of the adenoids than vice versa.

8. That the presence of adenoids has more to do with the presence of carious teeth than have mouth-breathing and palate shape, and that this is probably due to the increased tendency to oral sepsis in adenoid children.

9. That irregularity of the upper incisors is less a result of adenoids than of palate shape.

10. That the percentage of ear complications in adenoid children is about 10·8, and that adenoids are probably by far the most important factor in the ætiology of ear affections in childhood.

There is no need to compare my conclusions with those of Dr. Newsholme, but I cannot agree with his estimate that 5 per cent. only of the school-children would be suffering from symptoms calling for operation, presuming, of course, that the children referred to are the 600 out of 18,000. I am much more in agreement with my friend Dr. Dan McKenzie, that the percentage requiring operation is 30.

There is one thing that must be said in conclusion, for it has come repeatedly before me in my work as an officer of the L.C.C., and my experience has been endorsed by other otologists to whom I have spoken on the subject. It is that a large percentage of adenoid operations are inefficiently performed. Not a month passes without my being told by mothers that a child's deafness has been made worse by, or dated from, an adenoid operation. It is not the special hospitals that this complaint involves, but the large general hospitals and general practitioners in poor neighbourhoods. Even when the operation has been efficiently performed it would appear that in many instances the child is expected to recover hearing by itself, and no trouble is taken to follow cases up and to ensure that proper aural after-treatment is obtained.

Finally, the more I see of the treatment of adenoids and tonsils, the more I am convinced that the operation should be regarded as one of the highest importance and not as one so trivial that "anyone" can perform it.

I am, Sir, yours faithfully,
MACLEOD YEARSLEY, F.R.C.S.,
Consulting Aural Surgeon to the London County Council, &c.

Wimpole-street, W., Sept. 4th, 1925.

RADIATION FOR CARCINOMA:

MR. BONNEY'S CHALLENGE.

To the Editor of THE LANCET.

SIR,—I perceive from your report of the proceedings of the Section of Gynæcology at the B.M.A. annual meeting that Mr. Victor Bonney has been at it again. The mere mention of the word "radiation" appears to make him see red. Speaking of cases of carcinoma of the uterus with carcinomatous glands, Mr. Bonney said (THE LANCET, Sept. 5th, p. 498):—

> "He did not use radium beforehand as a routine, though he had operated on a good many cases in which it had been so used with the idea of making the growth removable. Those who said it could do this did not know the limits of operability. It did nothing of the sort, but on the contrary made the operation much more formidable on account of the intense fibrosis set up, which so welded the surrounding tissues to the growth that all planes of cleavage were lost."

If Mr. Bonney goes on at this rate (and he *does* go on, as his later remarks will show) his name will become a bogy with which to frighten young radiologists at their mother's knee! I am not specially concerned to take up the cudgels for radium as a pre-operative treatment, as I think it is less easily controlled than X rays, and may, unless very skilfully handled, cause actual tissue necrosis, with resultant extensive scarring. But Mr. Bonney does not confine his hostility to radium. He goes forth with bell, book, and candle, reciting a kind of Athanasian Creed which includes radium, X rays, and their advocates in one comprehensive damnation.

Now, if there is one thing firmly established in radiotherapy, it is that X rays in suitable doses have the power to cause the absorption of pathological fibrous tissue. Keloid melts away under their influence, and the tense bands of a Dupuytren's contraction become softened. The X ray, it is true, *does not* distinguish between fibrous tissue which is the result of disease, and adhesions which have been deliberately provoked by the surgeon. In a case published some years ago an intensive dose of X rays was given to a patient in whom a ventrofixation of the uterus had been successfully performed 12 months previously. Within a few weeks of the irradiation the adhesions to the abdominal wall gave way, and the original prolapse recurred. This case was quoted by a surgeon to illustrate the dangers of X ray therapy; in reality it was an excellent proof of the power of X rays to dissolve fibrous tissue. That this particular result was not the one aimed at does not in any way invalidate the demonstration. I am frequently called on by my surgical colleagues to attempt to render an inoperable case operable, and in many instances I am able to cause a fixed growth to become movable. This is a statement which it is quite obvious that no responsible medical man would make unless he were prepared, if necessary, to produce independent surgical testimony as to its truth.

To quote Mr. Bonney further (p. 400):—

> "His experience of this treatment (deep X rays) both for primary and secondary growths was most disappointing... No one was more anxious than himself to find a better method of treating carcinoma of the cervix than operation, but there was no sense in the advocates of radiation carping at the results of surgery until they had produced a series of figures comparable with those he had just put before them.... What was needed was the publication of a British series of not less than 100 cases treated by *radiation, in all* of which at least five years had elapsed between the date of cessation of all treatment and the date of publication."

The idea of the British radiologist carping at the results of surgery makes one smile. If he has erred in the past it is by excessive deference to surgical views. *Damnat quod non intelligit* is not a fault which can be laid at his door. But Mr. Bonney issues a direct challenge. It is, however, one that he must know he is quite safe in making. To carry out such a test it would be *necessary* to secure 100 cases of pelvic cancer not of the moribund type, which the British radiologist usually sees, but similar to an average 100 of the cases which are now operated on. At present the sequence of events is this: The practitioner sends the patient to a gynæcological surgeon, who invariably recommends operation when this is technically possible. The radiologist sees only (1) the inoperable cases, (2) recurrences, and (3) a few patients who refuse operation. It is only from these latter that *statistics* such as Mr. Bonney asks for could be compiled, and I doubt if there are many radiologists who see 20 such cases in a life-time of practice. Is Mr. Bonney—is any gynæcological surgeon—prepared in his hospital practice to set aside 50 per cent. *of* all operable cases for five years or more in *order* to put the matter to proof? I think not. But unless those who control the cases are prepared to follow some such plan it is idle to taunt the British radiologist with the failure to produce statistics.

I *express no opinion* as to what the probable result of such a test would be. Personally, I have always advocated combination in treatment. My object has been to show that Mr. Bonney has issued a challenge which, through no fault of the *radiologist*, cannot be *accepted*.—I am, Sir, yours faithfully,

Harley-street, W., Sept. 5th. F. HERNAMAN-JOHNSON.

LONDON MEDICAL GRADUATES AND CONVOCATION.

To the Editor of THE LANCET.

SIR,—May I point out to all M.B.'s of London the significance of the amendment of Statute 41, Clause (ii), which was ratified by the King in Council in May last, and is now in force, which entitles every M.B. to be registered *as a member* of Convocation (and, subject to the Representation of the Peoples Act, 1918, places him on the Parliamentary roll for the University vote) immediately he or she graduates, provided the age of 21 years has been attained. Hitherto every graduate was compelled to wait three years from graduation, which produced the striking anomaly that, whereas graduates in other faculties (divinity, arts, law, music, science, in which graduation can be attained after a three years' course) might enter Convocation six years from *matriculation*, graduates in the medical *faculty* were compelled to wait eight and a half to nine years.

I pointed this out in the *Times* of Oct. 23rd last, and at the same time memorialised the faculty representatives and the present Member of Parliament for the University. They agreed that the existing anomaly called for removal, and accordingly a motion was framed, and put by Mr. Eason at the meeting of the Faculty of Medicine on Oct. 20th last, which called the attention of Convocation to this anomaly, and recommended the amendment of Statute 41, para. (ii) by the abolition of the probationary period of three years. This was carried unanimously, and was sent on to Convocation. Independently of this action Dr. James Mould, at the request of the Twentieth Century Society of London Graduates, placed a notice of motion on the agenda paper of the meeting of Convocation held on Jan. 16th, 1925. Convocation resolved in accordance with the *terms of Dr. Mould's* motion which was then forwarded to the Senate, and, as stated above, was finally approved by His Majesty in Council in May.

The link between the University and her graduates *needs strengthening* by every possible means, and now that our Alma Mater stretches out her hands in welcome, it behoves every M.B. to become a member of Convocation as soon as possible, and thus to take an active interest in the government of the University.

I am, Sir, yours faithfully,
CHARLES A. H. FRANKLIN, M.D. Laus.,
M.B., B.S. Lond.

Bickley, Kent, Sept. 7th, 1925.

SILICATE IN A HARROGATE WATER.

To the Editor of THE LANCET.

SIR,—Valuable therapeutic uses are attributed to silicate by Prof. F. Luithlen in the article annotated in your issue of August 22nd (p. 392). Luithlen there points out the importance of a proper balance between calcium and silicon in healthy tissue. A deficiency of silicate is said to result in decreased *elasticity* and certain senile conditions. Any natural medicinal source, therefore, containing silicate presents points of interest hitherto rather neglected, although Weber and Weber ("Climatotherapy and Balneotherapy," p. 341) refer to the therapeutic *influences* of this compound.

In the Harrogate John's Well we have a water which appears particularly suitable for the administration of silicate. Only in very rare cases does the silicate content of a natural water approach the calcium in amount, and a brief search discloses no instance in which the ratio Si/Ca is so high as in the John's Well. Results of analysis of John's water, expressed in terms of parts weight of ions per 100,000:

Specific gravity 16°/15° C.	1·00019	Calcium	1·83
Total solid matter	19·00	Iron	0·08
Sodium	1·04	Manganese	0·022
Potassium	0·20	Chloride	1·80
Ammonium	0·000	Silicate	3·54
Lithium	trace	Sulphate	0·86
Magnesium	0·87	Carbonate	14·2

The water is palatable and assimilable. It is hypotonic, having an osmotic pressure of about 130 mm. of mercury. Usually it is prescribed *for its* iron content, which is small, but as Bain and Edgecombe say of this spring ("Harrogate Waters, Baths, and Climate," p. 99): "There are certain patients so peculiarly susceptible to the influence of iron that, unless weak solutions easily assimilated are prescribed, the remedy has to be abandoned." The ration of silicate to calcium is 1·93.

I am, Sir, yours faithfully,
A. WOODMANSEY, M.Sc.,
Analyst, Royal Baths, Harrogate.

Sept. 4th, 1925.

MISQUOTATION.

To the Editor of THE LANCET.

SIR,—In the *Vaccination Inquirer*, the organ of the National Anti-Vaccination League, dated Sept. 1st, a statement has been made to the effect that at a meeting of the Natural History Society in Eastbourne I stated: "I would rather sleep with a case of small-pox than a case of influenza," and for having stated this I am alluded to as "Eastbourne's sensible M.O.H." It will interest your readers to know that this statement is a *part* of a sentence which was completed to this effect: "Because I have been vaccinated against small-pox and keep myself re-vaccinated from time to time."

The *Vaccination Inquirer* is, I understand, circulated to medical men, and the passage might very well give the impression that I did not believe in vaccination. The facts are that I was giving an address on vaccination and similar matters at the meeting of the Natural History Society, and was taking the opportunity of rubbing in the importance and advisability of vaccination and re-vaccination, explaining carefully the reasons for my doing so.

It is interesting to know that anti-vaccinators can take a part of such a statement as I made and twist it so that it would appear that my opinion is diametrically opposite to that which I stated in full at the meeting. The statement in the *Vaccination Inquirer* may not be a matter altogether of bad faith on the part of the writer in that paper, for his information was got from a local paper in which a contributor, who is a prominent anti-vaccinator, made the original statement.

I am, Sir, yours faithfully,

W. G. WILLOUGHBY,

Sept. 8th, 1925. Medical Officer of Health, Eastbourne.

⁂ We have received from the President of the National Anti-Vaccination League a pamphlet on the vaccination question, asking for assistance on the ground of "the power of the press in all matters." The power of the press is sadly minimised when misquotations of the sort complained of by Dr. Willoughby occur. Dr. Willoughby suggests that the editor of the *Vaccination Inquirer* was misled, but the error should be rectified now.—ED. L.

RHEUMATIC INFECTION IN CHILDHOOD.

To the Editor of THE LANCET.

SIR,—The leading article in your issue of August 15th (p. 341) seems to endorse the view of Dr. Robert Hutchison and others that rheumatic infection is not a poverty disease. But the figures given in the discussion do not appear to me to warrant their deduction. In 48 per cent. the wages, it is stated, do not exceed 7*s.* per head, or, say, for a family of eight a total of £2 16*s.* per week. Why, to house a family of eight decently the rent would be at least 16*s.*, whilst clothes, boots, &c., would amount to another 2*s.* per head or 16*s.* for all, to say nothing of paying into a club, saving for a rainy day, tobacco, entertainments, &c., so that there remains but 24*s.* to feed a family of eight for the whole week, and yet Drs. Coates and Thomas think this not poverty. How much milk at 10*d.* per quart is likely to be bought for such a household? Would any eggs at 4*d.* each ever be consumed by a single child? Yet such important lime-bearing foods as milk and eggs are essential for the good health of children.

In my investigations, which I have carried out with Dr. Tighe and which comprise more than 44 children, it was found that nearly all the post-rheumatic or post-choreic heart cases occurred in those who took neither milk nor eggs. I divide children into two classes—viz., milk-drinkers and non-milk drinkers. Of this latter class there are those who aggravate their poor intake of lime-bearing food by partaking largely of vinegar, sauces, and sour things generally, thereby helping still further to deplete the system of lime; this subclass I call the "acid class," from which in my experience all the cases of rheumatic fever and chorea arise.

The inadequate intake of lime and its aggravation by the consumption of acid and sour things constitute a predisposition which, in my opinion, requires but a protein sensitisation such as occurs when children are bitten by harvest bugs, midges, fleas, sand fleas, and the like, to give rise either to rheumatic fever or chorea.

I am, Sir, yours faithfully,

G. ARBOUR STEPHENS,

Consulting Cardiologist, Welsh National

Swansea, Sept. 6th, 1925. Memorial Association.

MOSQUITO CONTROL IN ENGLAND.

To the Editor of THE LANCET.

SIR,—Referring to the account, given in your issue of Sept. 5th (p. 526), of the formal opening at Hayling Island of the well-equipped building provided by Mr. John F. Marshall to house the recently constituted British Mosquito Control Institute, it is curious that although during the past 28 years enormous advance has been made in the control of mosquito-borne disease, and that British scientists, notably Sir Ronald Ross, have taken a leading part in this work, yet, with the exception of the now well-known investigations of Mr. Marshall, the subject of mosquito control in this country has been almost entirely neglected.

In the absence of endemic malaria the mosquito problem has not been such a vital question in this country as in many other places; at the same time, even in this country, there are numerous districts in which the residents suffer severely from the bites of these insects, and fatal results are by no means unknown. Apart, however, from serious injury to health, the nuisance and irritation caused by these insects become at times almost unbearable. The success which has attended the efforts of Mr. Marshall in Hayling Island is likely to lead to a demand for the adoption of measures for mosquito control in many other places, and to any of my fellow medical officers of health, upon whom may devolve the duty of dealing with the mosquito nuisance, I would suggest that an application to Mr. Marshall and his colleagues at the British Mosquito Control Institute would secure advice and assistance which would materially promote the success of their efforts in this direction. I can testify from personal experience both to the scientific and thoroughly practical character of the work which has been carried out at Hayling Island, and to the courteous and ready response to applicants for advice.

I am, Sir, yours faithfully,

A. MEARNS FRASER, M.D.,

Sept. 8th, 1925. Medical Officer of Health, Portsmouth.

MEDICINE IN RUSSIA.—About six million cases of malaria have been recorded throughout the Union of Socialist Soviet Republics in 1924. As a certain number of cases remain unrecorded this figure is a minimum. The death-rate did not exceed 5–6 per cent. of the total number of victims, even in the Caucasus and Astrakhan regions where malaria is most prevalent. The People's Commissariat for Health, and its provincial branches, carry on an anti-malaria campaign, having at their disposal 103 equipped malaria stations, six tropical institutes for scientific study, and a number of clinics served by a special staff. 75,000 kilogrammes of quinine have been imported to U.S.S.R. during this year, and 6000 kilogrammes have been distributed, free, to the population. In addition to this amount the "Zusstrah" (Central Organisation for the Social Insurance of Workers) has purchased abroad and distributed among the workers about 2000 kilogrammes of quinine.—To locate the leprosy centres in Siberia is the object of a scientific expedition which is leaving Irkutsk under the leadership of Dr. Perevodchikov. In his opinion one of such centres must exist east of the Baikal Lake: there are also indications that one lies in the region of Barbousin, in the Buriat Republic.

Medical News.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—An intensive course in General Medicine, Surgery, and the Special Departments will be given at the Westminster Hospital from Sept. 21st for two weeks. The Brompton Hospital will start a fortnight's course in Diseases of the Chest on Sept. 21st. Full particulars and syllabuses of the courses, together with the Fellowship programme, may be obtained from the Secretary, 1, Wimpole-street, London, W. 1.

OPENING OF THE MEDICAL SCHOOLS.—The following functions will be held in connexion with the opening of the undermentioned London medical schools:—

St Bartholomew's Hospital.—Old students' annual dinner, Thursday, Oct. 1st, in the Great Hall of the hospital. Chairman: Mr. J. Adams.

St. Mary's Hospital.—Past and present students' annual dinner, Monday, Oct. 5th, at the Connaught Rooms, Great Queen-street. Chairman: Mr. Leslie Paton.

Middlesex Hospital.—In the Queen's Hall, Thursday, Oct. 1st, at 3 P.M., prize distribution by the Hon. Sir Arthur Lawless; inaugural address by Dr. O. E. Lakin on Tradition in Medicine. Annual dinner, Thursday, Oct. 1st, at the New Criterion Restaurant, Regent-street. Chairman: Sir Arnold Lawson.

Westminster Hospital.—Inaugural address by Prof. A. E. Gardner, Thursday, Oct. 1st, at 3 P.M., in the board room of the hospital. After the address Prof. Gardner will unveil in the hospital laboratories a tablet commemorating the generous endowment of pathological research work by Mr. A. J. H. Carlill.

ROYAL DENTAL HOSPITAL OF LONDON.—The distribution of prizes to the school of dental surgery will be made by Sir John Bland-Sutton at the hospital on Monday, Oct. 5th, at 4 P.M.

UNIVERSITY OF LONDON.—Applications for the Julius Mickle Fellowship must be made before Oct. 1st. The Fellowship, which is of the value of at least £200, is awarded by the Senate to the man or woman who, being resident in London and a graduate of the University, has, in the opinion of the Senate, done most to advance medical art or science during the preceding five years.

UNIVERSITY OF DURHAM.—Post-graduate instruction will be held in clinical medicine, clinical surgery, and pathology on each Thursday from Oct. 1st to Dec. 10th, and courses in various special subjects will also be held weekly. A detailed syllabus may be obtained from Prof. R. Howden, College of Medicine, Newcastle-upon-Tyne.

UNIVERSITY OF PARIS: *Pathological Anatomy.*—An advanced course on this subject will commence on Monday, Oct. 5th, under the direction of Prof. G. Roussy, assisted by many distinguished collaborators from Paris and other medical centres of France. The course is open to French and foreign doctors and students and the fee is Fr.150. Full particulars and the syllabus may be obtained from Dr. Leroux, 21, Rue de l'École de Médecine, Paris.

INTERNATIONAL CONGRESS OF HYDROLOGY AND MEDICAL CLIMATOLOGY.—The eleventh congress of this series will be held in Brussels from Oct. 11th to the 13th, under the presidency of Dr. Modeste Terwagne. Full particulars may be obtained from the general secretary, Dr. René Beckers, 36, Rue Archimède, Brussels.

CARDIOLOGY.—A special two weeks' course in cardiology will be held at the National Hospital for Diseases of the Heart, Westmoreland-street, Marylebone, W. 1, from Oct. 5th to 10th. The course includes lectures, demonstrations, clinical and pathological. As the course will be limited to 10 participants, early application should be made to the Dean, Dr. B. T. Parsons-Smith, from whom copies of the syllabus may be obtained.

RONTGEN SOCIETY.—The following are the officers and members of council for the session, 1925–26:—President: Dr. F. W. Aston, D.Sc., F.R.S. Vice-Presidents: Dr. Robert Knox, Dr. N. S. Finzi, Prof. A. W. Porter, D.Sc., F.R.S. Hon. Treasurer: Mr. Geoffrey Pearce. Hon. Editor: Dr. G. W. C. Kaye, D.Sc. Hon. Secretaries: Dr. E. A. Owen, D.Sc., Dr. Russell J. Reynolds. Council: Dr. G. B. Batten, Dr. H. A. Colwell, Prof. J. A. Crowther, D.Sc., Dr. E. P. Cumberbatch, Mr. A. K. Glover, Dr. J. E. A. Lynham, Dr. J. M. Woodburn Morison, Dr. G. H. Orton, Mr. C. E. S. Phillips, Prof. S. Russ, D.Sc., Mr. W. E. Schall, Dr. G. Shearer, D.Sc.

ROYAL PHOTOGRAPHIC SOCIETY.—The annual exhibition will be held at the house of the society, 35, Russell-square, London, W.C. 1, from Sept. 14th to Oct. 24th. Admission is free.

METROPOLITAN EAR, NOSE AND THROAT HOSPITAL.—The eighty-sixth annual report of this institution records (in tabular form) a successful year of work. Over 3000 out-patients and nearly 600 in-patients have been received and treated for conditions ranging from wax in the ear to lupus of the fauces, and from globus hystericus to ethmoidal sarcoma. Two special evening clinics for pensioners are still being held, and nearly 200 ex-soldiers have been treated. The average total cost of each in-patient is now £3 per week, a decrease of £1 4s. 0d. on 1923.

THE LATE DR. B. W. DAKERS, OF KENYA.—Bernard William Dakers, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., died at Kisumu, Kenya Colony, on July 10th. Dr. Dakers qualified in 1906 and entered the Kenya Civil Service in June, 1920. He was the first medical officer to be stationed in South Kavirondo. He was employed throughout in native reserves. There he won, by his sympathy and tact, the confidence of the local native population, and was very largely instrumental in popularising European methods of treatment.

NEW BETHLEM HOSPITAL.—It is stated in the annual report of Bethlem Hospital that the Monks Orchard estate, to which the institution is to be removed, cost a little under £30,000. The average weekly cost of the patients was £5 1s. 7d. The scarcity of female nurses (in the words of the report) "still causes much anxiety." One half of the patients pay amounts ranging up to £3 3s. per week.

BELGRAVE HOSPITAL FOR CHILDREN: PAYING PATIENTS.—Early next year a ward is to be opened for the admission of patients whose parents can afford to pay the cost of maintenance (about £3 per week) and a small fee to the physician or surgeon in attendance. This cannot be done until the new west wing, now being built, is finished. This wing will afford sufficient accommodation for the nursing staff, which is now inconveniently housed in three different buildings.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL: MIDWIFERY TRAINING.—The annual report of this hospital shows that out of 123 pupil midwives who sat for the C.M.B. examination only four failed. Henceforward the period of training will be 12 months instead of six, save in the case of pupils who hold a certificate of three years' training in general nursing, in which case the period will be six months instead of four as hitherto.

A FOUNDER OF HOSPITALS.—Canon J. O. Stephens, who died last week at the age of 93, while holding the benefice of Savernake in 1866 founded and endowed Savernake Cottage Hospital, Marlborough, which provides medical and surgical help for 54 rural parishes in Wiltshire and Berkshire. When, in 1870, he left Savernake to become rector of Blankney in Lincolnshire, he was the prime mover in the foundation of the Alexandra Hospital at Woodhall Spa.

A RECOVERY HOSPITAL FOR HUDDERSFIELD.—The board of management of Huddersfield Royal Infirmary have purchased for £10,000 the Green Lea estate, Lindley, with the intention of creating a recovery hospital. It is proposed that, for the present, surgical cases shall be removed thither for recovery, but that eventually the existing infirmary itself shall be used as an out-patient and casualty hospital, in patients being treated at Lindley, which is 700 feet above the sea. The Green Lea estate is between 13 and 14 acres in extent.

LEEDS PENSIONS HOSPITAL.—Rapid progress is being made with the new Military Hospital at Gledhow, Leeds, which, when completed, will be a centre for ex-Service men from the north of England. It will accommodate between 200 and 300 patients and 80 nurses, and will cost £100,000. The buildings will include a cinema hall.

THE LATE DR. W. B. LIVERMORE.—William Barclay Livermore, M.D. Aberd., of Exeter, died on August 21th in a Plymouth nursing home of cerebral hæmorrhage at the age of 62. Born in Aberdeenshire, he was educated in Elgin and at the Aberdeen Gymnasium. He received his medical training at Aberdeen University and at Westminster Hospital, graduating M.B., C.M. Aberd. in 1883. After some experience in private practice at Cleckheaton, Yorkshire, he took up the study of tuberculosis and was appointed medical superintendent to the Devon and Cornwall Sanatorium for Consumptives, Didworthy, South Devon. Under Dr. Livermore's administration, which extended over 15 years, this institution increased in capacity from 20 beds to 76. On his retirement he was appointed to the consultant staff.

ST. BARTHOLOMEW'S HOSPITAL WAR MEMORIAL.—The archway beneath the north wing of the hospital is to be utilised for the erection of a war memorial to St. Bartholomew's men.

ROTHERHAM HOSPITAL.—On Sept. 7th Princess Mary opened a much-needed extension of Rotherham Hospital, which was last enlarged nearly 30 years ago. The additions have cost £20,000, practically the whole of which has already been subscribed.

PRESENTATION TO A MEDICAL MAN.—Dr. W. J. L. Ffrench, of Barnetby, Lincs, who has been identified very prominently with the public life of the district for 30 years, was recently presented with a silver salver and a cheque for £207.

THE Hastings Town Council has decided to acquire the lease of the White Rock Bathing Establishment, now leased by the corporation to a private organisation which is ready to surrender the balance of its term. If the council carries out its design, it should take over the baths as from Sept. 30th, when it will be necessary to spend a large sum to bring the establishment up to high standard, and this policy is to be followed.

THE PRINCE IN ARGENTINA.—H.R.H. the Prince of Wales recently visited the "Oxo" supply ranches in Argentina. Some 15 or 16 years ago a special commissioner of THE LANCET was sent to Argentina to investigate the circumstances in which the "Oxo" products were prepared, and his long and interesting report will as well repay study to-day as then. (Vide THE LANCET, 1908, ii., 1233.)

THE "PAUPER TAINT."—Mr. Richard Turley's seat on the Leeds board of guardians has been declared vacant because he has become an in-patient of the Poor-law infirmary. Mr. Turley was taken thither in a semi-conscious condition because there was no bed available at Leeds General Infirmary. He is a paying patient, yet under the Local Government Act of 1894 he has not only lost his seat but is disqualified for re-election for 12 months.

KEIGHLEY'S CHILD CONVALESCENTS.—Sir Prince and Lady Prince-Smith have provided and opened the Southburn Children's Home in the Yorkshire wolds near Driffield for child convalescents from Keighley. The former residence of Sir Prince-Smith's land agent has been adapted for the purpose, and the inmates are to be "children of deserving parents who cannot afford to pay for convalescent treatment," who will be taken either from Keighley Hospital or upon a doctor's recommendation.

THE LATE DR. J. MURDOCH BROWN.—James Murdoch Brown, M.D., F.R.C.P. Edin., died at his residence in Edinburgh on Sept. 3rd. Although he had been retired from active practice for many years, he was at one time one of the best known practitioners of the city. He graduated M.B., C.M. at Edinburgh University in 1874 with first-class honours and was Ettles Scholar of his year, and in 1878 became a Member of the Royal College of Physicians of Edinburgh, obtaining the Fellowship two years later. He gained the M.D. Edin. in 1897. Dr. Brown for many years held the office of justice of the peace for the county of Edinburgh.

DONATIONS AND BEQUESTS.—Sir William Northrup McMillan, of St. Louis, Missouri, U.S.A., and of Kenya Colony, left among other bequests $250,000 to the Scott Sanatorium, Nairobi, British East Africa, as an endowment.—Mr. Richard Fenwick, Edgbaston, Birmingham, left £6000 to the University of Birmingham for a scholarship or scholarships upon such terms and conditions as the governors in their discretion should think fit, and £200 each to the Birmingham Maternity Hospital and the Birmingham Royal Institution for the Blind.

Appointments.

CAPON, NORMAN BRANDON, M.D. Liverp., has been appointed Hon. Physician to the Royal Southern Hospital, Liverpool.

Vacancies.

For further information refer to the advertisement columns.

Birmingham General Hospital.—Asst. S. £50.
Blackburn County Borough.—Asst. M.O.H. £600.
Bradford Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.
Brighton County Borough Sanatorium.—Res. M.O. £350.
Brighton, New Sussex Hospital for Women and Children.—Hon. Radiologist.
Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—H.S. £100. Also Jun. H.S. £50.
Chester Royal Infirmary.—Hon. Asst. S.
Colwyn Bay and Colwyn Urban District Council.—M.O.H., &c. £750.
Denbigh County Council.—Asst. M.O. £600.
Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £100.
Durham County Council.—Asst. Sch. M.O. £600.
Evelina Hospital for Children, Southwark, S.E.—H.P. at rate of £120.
Exeter, Royal Devon and Exeter Hospital.—H.P. and Asst. H.S. Each at rate of £150.
Glasgow Royal Infirmary.—Supt. £800.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Asst. P.
Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each at rate of £50.
Hospital for Tropical Diseases, Endsleigh Gardens, N.W.—H.P. At rate of £110.
Lambeth Parish Hospital, Brook-street, Kennington, S.E.—Jun. Asst. M.O. £200.
Lister Institute of Preventive Medicine, Chelsea Bridge-road, S.W.—Jenner Memorial Research Studentship. £250.
London Hospital, E.—First Asst. and Referee to one of the Five Surgical Firms. £400.
Macclesfield, Cheshire County Mental Hospital, Parkside.—A.M.O. £350.
Manchester and District Radium Institution.—Asst. Radiologist. £500.
Manchester Royal Infirmary.—Res. Clin. Pathologist. £50 for six months.
Manchester, St. Mary's Hospitals.—Three H.S.'s. Each at rate of £50.
Manchester University.—Asst. Lecturer in Chemical Pathology. £400.
Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—Anæsthetist.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Asst. S.
Nottingham Children's Hospital.—Res. H.P. and Res. H.S. Each at rate of £150.
Pharmacological Laboratories of the Pharmaceutical Society of Great Britain.—Director. £1200.
Prince of Wales's General Hospital, Tottenham, N.—H.S., Spec. H.S., and H.P. Each at rate of £150. Also Jun. H.S. and Jun. H.P. At rate of £110.
Radium Institute, 16, Riding House-street.—Cancer Research Worker. £500.
St. Pancras Hospital, &c.—Sen. Asst. Med. Supt. £400.
Singapore, Straits Settlements.—Two Asst. Health Officers. $7200.
South London Hospital for Women, South Side, Clapham Common, S.W.—H.P., three H.S.'s. Each at rate of £50. Clin. Asst. £1 1s. per attendance. S. to Ear, Nose, and Throat Department.
West London Hospital, Hammersmith-road, W.—H.P. and Two H.S.'s. Each at rate of £100.
Whipps Cross Hospital, Leytonstone.—Specialist Consultant in Light Treatment. £300. Res. Asst. M.O. £350.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments for Certifying Factory Surgeons at Purfleet, Essex, and Ramsgate, Kent.

Births, Marriages, and Deaths.

BIRTHS.

GREEN.—On Sept. 1st, at Chippenham House, Monmouth, the wife of J. G. Green, M.B., B.Ch., B.A.O. N.U.I., F.R.C.S.I., of a daughter.

MARRIAGES.

CURRY—REA.—On Sept. 5th, at St. Clement Danes Church, Strand, Henry Donald, eldest son of the late H. G. Curry and Mrs. Curry, of Stradella-road, Herne Hill, to Helen Gladys Rea, L.R.C.P.I. and L.M., L.R.C.S.I., younger daughter of J. C. Rea, of Howth, Co. Dublin.

HUME—POOLE.—On Sept. 3rd, at Westcliff-on-Sea, John Basil Hume, M.B., F.R.C.S., to Marjorie Constance, daughter of Mr. and Mrs. Fredk. Poole, of Westcliff.

DEATHS.

BATTY.—On Sept. 1st, at Broadoak Cottage, Newnham, Brig.-Surgeon Richard Hamilton, I.M.S. (retired), L.R.C.S.I., L.S.A., aged 84.

BROWN.—On Sept. 3rd, at Strathearn-road, Edinburgh, James Murdoch Brown, J.P., M.D., F.R.C.P. Edin., aged 77 years.

CHURCHWARD.—On Sept. 4th, suddenly, at Selhurst-road, South Norwood, Albert Churchward, M.D. Brux., M.R.C.S. Eng., M.R.C.P. Edin., L.S.A.

ESKRIGGE.—On August 31st, Richard Bertram Eskrigge, L.R.C.P. Edin., and L.M., M.R.C.S. Eng., Royston, Barnsley, Yorks, aged 62.

LOVE.—On Sept. 6th, at Downpatrick, Ireland, Gilbert Love, M.D., B.Ch., B.A.O. R.U.I., of Great Budworth, Cheshire, the result of an accident.

ORR.—On Sept. 2nd, at Templepatrick, Co. Antrim, James Orr, L.R.C.P. & S. Edin., M.O. and M.O.H. Templepatrick Dispensary District.

RENTOUL.—On Sept. 3rd, at Hartington-road, Liverpool, Robert Reid Rentoul, M.D. R.U.I., L.R.C.P. & S. Edin., M.R.C.S. Eng., aged 70.

N.B.—A fee of 7s. 6d. is charged for the insertion of **Notices of** *Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

NATIONAL INSTITUTE FOR THE BLIND.

THE report of the executive council of this institution for the year ended March, 1925, is a gratifying record of the way in which the care of the blind has regained the support of the general public. After passing through lean years, the Institute is now in a position to extend its activities in the wider fields of former years; during the period under review, a third "Sunshine House" (Blind Babies Home) has been opened at Leamington Spa, Warwickshire, a convalescent and holiday home has been established at St. Leonards-on-Sea, Sussex, the publication of Braille literature has been considerably increased, and the price of Braille books and periodicals reduced. Among the many training departments of the Institute the school of massage is one which offers particularly good opportunities, for massage is pre-eminently a profession in which the blind can compete with the sighted. This school is recognised by the Board of Education. The special training given to blind students in medical electricity is in charge of Dr. Murray Levick, and a blind masseur who has specialised in the subject has been appointed on the staff to give instruction in the theory of electricity and the construction of batteries. The total number of blind civilian masseurs and masseuses on the register of the massage department is 100, and great care is given to the settlement of pupils after qualifying. During the past term Sir Jenner Verrall delivered a special course of lectures to blind students on modern orthopædics. The report, which incorporates the annual reports of the Clifton Home for Blind Women, the Home Teaching Society for the Blind, and the Moon Society makes stimulating reading, and concludes with an invitation to all interested to visit the headquarters of the Institute at 224-26-28, Great Portland-street, London, W. 1.

THE WEB OF LIFE.

THE first fortnightly part has just appeared of a new serial by Prof. J. Arthur Thomson entitled "A New Natural History: Nature's Wonder-land." Justifying his ambitious title Prof. Thomson points out how the study of living creatures is undergoing a subtle change and how our knowledge must be readjusted to meet this change. His own attitude towards animal life has brought him to think of animals not only as threads in a wavering web of life but as personalities of a sort which may share in their own further evolution. The first instalment, which is profusely illustrated, opens with a chapter on the Web of Life, in which the author sets out the linkage between bird and plant in the relation between missel-thrush and mistletoe, and the more complicated alliance in the petiole of a species of laburnum between plant, beetle, and mealy-bug. How such an alliance began he hardly attempts to explain, and the chapter ends on a note of inquiry which may well induce the reader to pursue the subject further. The great value of Prof. Thomson's work seems to us to lie in his power of setting out broad principles in an engaging manner, producing in his readers a taste for investigation on their own account. Moreover, the alliance of visible organisms in the web of life may be of help to the reader in visualising the inter-relations between microscopic cells on which organic function within the species depends. The work is to be completed in about 20 fortnightly parts at the price of 1s. 3d. each. (Geo. Newnes.)

NURSERY PSYCHOLOGY.

A SERIES of six lectures will be held this autumn at Carnegie House, 117, Piccadilly, on Everyday Psychology in the Nursery. These lectures are a further series of those held in the summer and the previous autumn, which proved to be a success. They will be welcomed by mothers who are anxious to hear the best authorities on various aspects of child life and difficulties. Amongst the lecturers are Dr. Hector Cameron, Sir Bruce Bruce-Porter, and Dr. Leonard Williams. There will be one special lecture for mothers and fathers on Family Discipline, by Dr. H. Crichton-Miller, on Thursday, Dec. 10th, from 6 to 7 P.M. The fees for these lectures are 7s. 6d. for any single lecture, or £3 for the series of lectures, and 15s. for two tickets for the special lecture by Dr. Crichton-Miller. The lectures will be under the headings of the Psychology of Infancy; Dangers of Tradition in the Nursery; Heredity and Environment; Habits and Subconscious Mind; Temperament; and Problems of School Age. These lectures take place on Thursdays, commencing Oct. 29th, at 3.15 P.M., and time is given at the end of each lecture for questions to be asked. Tickets may be obtained from Viscountess Erleigh, 65, Rutland-gate, S.W. 7, and Mrs. Ernest Shaw, 65, Conduit-street, W. 1.

THE PROFESSIONAL CLASSES AID COUNCIL.

UNDER this name the Professional Classes War Relief Council, instituted in October, 1914, has continued since 1920 its valuable work among those unpensioned sufferers from post-war conditions known as the new poor. How necessary such work is can be gathered from the fourth annual report of the Council for the year ending April, 1925, during which period 680 applications for help were received. The Council gave financial assistance—in many cases considerable—to 150 families, thus benefiting 314 individuals, and, in addition, 305 were advised where to obtain help. The scope of the Council's work is entirely dependent on the extent of the financial support it receives, and subscriptions will be welcomed by the treasurer at 251, Brompton-road, London, S.W. 3.

NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

THE Society's forty-first report shows the encouraging fact that neglect of and cruelty to children is gradually decreasing. The proportion of cases reported by the public is 62·5 per cent., larger than ever before, while the proportion discovered by inspectors is lower than in any previous period. In 1898 there were 2192 prosecutions and in 1924 there were 882. In recent years there has been a steady increase in the number of parents themselves seeking the advice and aid of the Society. There has also been a reduction in the number of instances where the children have had to be removed from the care of their parents. The conditions of life for children on canal boats is still unsatisfactory, and the Society has prepared a statement of facts for submission to Members of Parliament. It is hoped to secure legislation excluding children of school age from canal boats. The Guild of Good Courage consists of girls and young women who have been in the Society's legal custody as children and like to continue their association; it has a membership of 99. The medical branch has dealt with 700 cases, ranging from defective eyes and teeth to venereal disease, epilepsy, and chorea, and many cripples have been successfully operated on. A dinner in aid of the funds of the Society is to be held at the Guildhall on Nov. 25th. H.R.H. the Prince of Wales has graciously consented to preside and Sir W. Joynson-Hicks will speak. As the report says: "There is really no limit to what can be done to make life endurable for children if only all who are concerned in their welfare will coöperate to this end. Knowledge spreads slowly, and every time a new helper is secured the possibility of further usefulness is extended."

A GENEROUS OFFER.

A CORRESPONDENT writes: "A gentleman in a luxuriously appointed motor-car, whom I lately met on Exmoor, handed me a prodigious page of advertisement, containing an offer that should not be kept for one moment from the knowledge of your readers. You are too prejudiced to regard my plea for an open mind; yet I may remind you that these are days of overcrowding and competition when many a young man finds it hard to get his foot upon the ladder of success: £1000 per annum will be paid by my motoring acquaintance as salary to a qualified medical man who should possess the following qualifications. He must be able to make the blind to see, the deaf to hear, and the lame to walk. These biblical qualifications must be reinforced by ability to make flesh grow on withered limbs at the rate of a quarter to half an inch—whether this growth refers to thickness or superficies is not clear (as you will see by the advertisement which I enclose), but from hints dropped in conversation by the advertiser I infer that thickness is meant. Further, the applicant must be capable of curing 'undeveloped brain'; a vista of psychological possibilities thus opens into infinity. Two of the remaining qualifications required in the successful aspirant are a complete summary of professional competence—he must be able 'to inform patients what is the nature of their complaint, and its duration.' Here the power of diagnosis comes in. Lastly, it seems that he should be able to subdue pain in his patients without the use of drugs or anæsthetics, and above all to transmit vitality without contact. Apparently he is not expected to possess these abilities, but to acquire them by contact with the inventor, who states that 50,000 people have been already successfully treated and are walking testimonials to magnetic treatment. For his position will be that of an assistant who must submit to all rules and obey all regulations laid down by his principal and must act constantly as his locum tenens, showing as good a percentage of cures by pursuing the same methods."

As the advertiser succeeds in curing vast series of cases of "undeveloped brain" his business will diminish in ratio; so along one line of his activities we wish him luck. But we can hardly imagine any newspaper conducted by an editor with a brain sufficiently undeveloped to sanction the publication of this advertisement.

OBLITERATION OF TATTOO MARKS.

To the Editor of THE LANCET.

SIR,—Some years ago a patient of mine, a young woman, was tattooed on both legs. The present fashion of short skirts and thin stockings make the marks unduly prominent. Is there any method by which tattoo marks may be obliterated? I shall be grateful if any of your readers can tell me.

I am, Sir, yours faithfully,

Sept. 4th, 1925. M.B., &c.

THE PATIENT AS DIAGNOSTICIAN.

To the Editor of THE LANCET.

SIR,—For the information of my colleagues in London may I bring forward this story. A certain medical man in London is advising a patient, while travelling, to obtain the services of a local medical man every week wherever he may be for the purpose of injecting hypodermically a quack nostrum for the cure of a certain disease. In my case the patient met with a flat refusal and a letter followed to the London practitioner informing him of the fact. I may say that in his letter this doctor stated he was using this stuff "at the patient's own risk and responsibility"—a glaring irregularity in my opinion.

I am, Sir, yours faithfully,

Blackpool, Sept. 3rd, 1925. PERCY HOWARD DAY.

BRITISH HEALTH RESORTS.

WE have received a communication from Mr. Lyman D. Davis, Chairman of the Foreign Relations Committee of the Anglo-American Hotel Association, in which he pays a tribute to British holiday resorts from the point of view of an American "whose business has been for many years past connected with a number of the best known pleasure resorts in Europe and America." The Briton may decry his own pleasure resorts, both inland and coastal, but when it comes to the point of deciding where to spend his holiday he prefers a home resort, and when he travels abroad he does so for knowledge rather than enjoyment. In Mr. Davis's opinion all our possible continental competitors, in spite of their vigorous advertising, have been knocked out "because the facilities provided by the hotels and railway companies, town for town and village for village, are more complete and incomparably better and safer in Britain than in any other part of Europe." It is refreshing in these days to find anything British extolled for its own sake, and Mr. Davis's encouraging words will be appreciated.

THE DISINFESTATION OF LIVING SPACES.

To rid living spaces of insects and vermin is often difficult and as yet no standard method has been agreed upon. Hydrocyanic acid can, under careful regulations, be safely used in ships in harbours, but it is hardly suitable in barracks and tenements. For destroying rats and their fleas as well as other insects on ships sulphur has proved efficacious if the ship is thoroughly sealed down for six hours, but sulphur is not without its inconveniences. We are glad therefore to find in the *Journal of the Royal Army Medical Corps* for July a report by Major D. Reynolds on Disinfestation of Rooms by Formalin. He tells us that he has secured complete destruction of bugs in infested rooms when employing, as a minimum, 2 pints of formalin (40 per cent. formaldehyde) per 1000 cubic feet, poured on 2 lb. of a mixture of one-fifth quicklime and four-fifths bleaching powder, in a warm (70° F.) and damp (70 per cent. humidity) atmosphere. The vapour is allowed to act for at least 24 hours. Unfortunately, the question of cost is not discussed; 3 lb. of sulphur would cost 7*d.* at current wholesale prices, but 2 pints of formalin would be 3*s.*, plus the cost of the bleaching powder. It would be a help to medical officers of health and others concerned in the planning of disinfestation work if authors when describing new large-scale methods would mention the cost per 1000 cubic feet at which, in their experience, the methods they recommend have been carried through, differentiating if possible the cost of the materials from that of the labour employed.

CASTRATION THREATS TO CHILDREN.

WE have received from a lay correspondent an account of the disastrous effects of a castration threat directed towards himself when 3½ years old, as a punishment for an exhibitionist act. The memory of this he claims to have recovered by a process of self-analysis, and he is emphatic about the evil influence of such threats in connexion with the infantile tendency to exhibitionism, declaring that not more than two or three boys out of every ten escape some threat of this nature. This situation he links with the "castration complex," believed by psycho-analysts to be a frequent factor in mental disturbances of later life, and he suggests that parents should tell the two-year-old boy that he must not expose his genitals, but he is not to be frightened if anyone makes a cutting off threat against these parts, whilst servants and others should be warned against making the threat, though the child is to be smacked on the buttocks, if necessary, to check the forbidden behaviour. If our correspondent's view of the results of the threat be correct the remedy seems, on psycho-analytical grounds, to be equally inadvisable, for corporal punishment of this nature has been known to arouse perverted tendencies. Assuming that children pass through an exhibitionist phase it would surely be best to regard it as unemotionally as we regard other childish peccadilloes; we do not attach great emotional value, for example, to the offence of throwing food upon the floor and yet children quickly learn that "it isn't done." The castration threat may well ferment in the childish mind and is to be condemned; our aim should be to avoid feeling or showing emotional reaction towards behaviour which is nothing more than a passing phase, but may, if psycho-analytical findings are sound, become a source of serious trouble if excessive emotion is attached to it. Our correspondent has little doubt himself that the findings obtained by careful psycho-analysis are sound although the process is frequently painful.

Oil Fuel at the London Hospital.—The governors who, a few years ago, refused to replace coal fuel with oil have now reversed their decision and have decided to build a central boiler establishment to serve the whole of the hospital, the fuel being oil. There are still 101 closed beds in the hospital.

Messrs. Kelvin, Bottomley and Baird, Ltd., 51–52, Fenchurch-street, E.C. 3, have published a new eight-page list of apparatus for ultra-violet light therapy. Their full catalogue is in course of preparation. A copy will be sent on request to anyone interested.

X. Y. Z.—The medical statisticians present at the luncheon given by the Government on August 18th were: Dr. S. Rosenfield (Austria), Dr. Camille Jaquart (Belgium), Dr. H. J. Hansen (Denmark), Dr. T. H. C. Stevenson (England), Dr. Martti Kovero (Finland), Dr. M. Huber (France), Dr. E. Roesle (Germany), Dr. Gunnar Jahn (Norway), Dr. J. C. Dunlop (Scotland), Dr. E. H. N. Arosenius (Sweden), Dr. Marcel Ney (Switzerland), Dr. W. H. Davis (United States), Dr. A. Aguirre-Sayago (Chili), Dr. Martin Kacprzak (Poland), Mr. K. Stouman, and Mr. J. Pagnod (League of Nations).

THE British Dyestuffs Corporation, Limited, of 70, Spring-gardens, Manchester, have sent us a price list of fine organic chemicals for research work, which also includes a list of indicators, microscope stains, medicinal and photographic chemicals. The stains have been prepared from selected dyes tested at the Manchester Laboratory of Applied Pathology and Preventive Medicine. The indicators offered range in a complete series from pH nil, e.g., naphthol yellow S, to pH 13, e.g., Titan yellow. The Corporation were the original manufacturers of acriflavine in this country, and euflavine is now offered, being the same compound with one molecule of HCl removed. Auramine, put up in solution as glauramine, is believed to be one of the most powerful antiseptics ever produced. New products of the urea type have also been elaborated and tested.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 14th, to SATURDAY, Sept. 19th.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars. Daily instruction in the Out-patient Department from 2.30 P.M. Special demonstration of cases on Tuesday, and a Venereal Clinic on Tuesday and Thursday from 5.30 to 7 P.M.—THE INFANTS HOSPITAL, Vincent-square, S.W. Special Course. Lectures and demonstrations every afternoon. "Round Table" consultation on Friday, and on Saturday a visit to the Home for Blind Babies.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross. Clinical demonstration every afternoon from 2 o'clock with special demonstration three times a week

Hunterian Lecture

ON

SOME DISORDERS OF THE LARYNX.

Delivered at the Royal College of Surgeons of England

BY V. E. NEGUS, M.S. LOND., F.R.C.S. ENG.,
JUNIOR SURGEON TO THE THROAT AND NOSE DEPT. OF KING'S COLLEGE HOSPITAL.

John Hunter studied the circulation of blood through the lungs, and with his accustomed practical genius he exposed part of the lungs of a dog and watched the changes taking place in them under conditions of artificial respiration maintained by specially constructed bellows. He has left on record the observations he made,[1] and writes these words:

> "The diminution of the heart's motion upon stopping respiration does not depend upon the immediate impression of improper blood on the left auricle and ventricle as a sedative, but upon the sympathetic connexion which exists between the heart and lungs (one action ceasing the other also ceases); which sympathy is established, because if the heart were to continue acting it would send improper blood into the body, by which it can be supported only a little while. The right auricle and ventricle also cease acting, although not so early, and for the same reasons; because on the cessation of the function of the lungs the blood cannot receive any benefit in passing through them. These actions and cessations are all dependent on life and the connexion of one action with another."

No better words could possibly be found to express the object of the present paper. I shall attempt to describe what I imagine to be one of "the connexions of one action with another," and to show how the larynx serves an important function in preventing the heart from sending "improper blood" into the body. I wish to add what I imagine to be one link to the work carried out by Hunter and only hope that my efforts are worthy of the illustrious investigator whose researches were based on close observation, reasoned interpretation, and an earnest desire for the discovery of truth.

I wish to express once again my indebtedness to Sir Arthur Keith, who has given me facilities for research and has been ready at all times to give me advice and information derived from his store of knowledge. He pointed out to me the importance of the respiratory movements of the glottis in their bearing on the circulation of the blood, a subject to which he has given considerable attention. I am also extremely grateful to Prof. R. J. S. McDowall, both for allowing me the opportunity of making experimental observations on animals, and also for supplying facts and experimental evidence relating to respiration and circulation.

A large source of knowledge has been supplied by Prof. J. S. Haldane's book on Respiration[2]; so many of the observations recorded are derived from this authority that it would be confusing to refer to each one as it occurs. I have attempted to correlate the various observations and to add my humble contribution to the elucidation of that "sympathetic connexion" described by the great master.

NORMAL MOVEMENTS OF THE LARYNX.

A study of the anatomical structure of the larynx of all lung-breathing animals is but a means to the understanding of the physiology of the organ. It is only by the evidence of comparative anatomy and physiology that the multifarious functions of this important part of the body can be explained, and I intend to make use of what information is available from the literature and from personal observation in dealing with the question of respiratory movements of the glottis.

The movements of the larynx are many. The whole organ ascends in the neck on deglutition and phonation. The laryngeal aperture closes on swallowing, by virtue of contraction of its muscular sphincter. The vocal cords come together during phonation, and for the alteration of intrapulmonary and intrathoracic pressure in both a positive and negative direction. The ventricular bands come together when it is desired to raise intrathoracic pressure to a great degree. And finally, the vocal cords open and shut to a greater or lesser degree during respiration, in proportion to the force of breathing.

RESPIRATORY MOVEMENTS AT THE GLOTTIS.

It is recorded in many physiological text-books and in other works that the glottis opens to a certain extent on inspiration and partially closes on expiration; as far as I know, no reason is given for these movements. As they cannot be accidental it seemed necessary to discover their object; brief allusion was made to the subject in my Arris and Gale lecture delivered in 1924.[3] In the present paper it is intended to study the subject more fully, to add whatever new information has been collected, and to apply the physiological findings to the elucidation of certain conditions caused by disease. At the beginning of inspiration the glottis opens to a certain degree, which increases in direct relation to the force of inspiration; at the beginning of expiration it closes partially, and under certain conditions is almost completely closed. Exception may be taken to this statement, because in many individuals in the resting condition the glottis is apparently immobile during the phases of respiration, as pointed out in particular by Semon.[4] In all individuals, however, it seems probable that respiratory movements occur as soon as any exertion is undertaken, while in animals such as cats, dogs, and rabbits, and in birds, reptiles, and amphibians, the opening and closure is to be seen at all times.

In those human beings who do not show variations in size of the glottic aperture during the phases of inspiration and expiration, there is, however, a change in size when an increase or decrease in depth of breathing occurs. This change in size is all that is essential to substantiate the explanation given later on as to the mechanism probably at work. Although alterations in size when present add the fine adjustment to regulation of gas exchanges, it is not necessary that they should occur during the different phases of respiration.

The mechanism is extremely complicated, but without discussing in detail the many factors at work, an attempt will be made to give a short description of the chief objects of the movements as they apply to man.

Relation of Respiratory Movements at the Glottis to Alveolar CO_2 Content.

The main function seems to aim at keeping the reaction of the blood constant. This is attained by the provision of a fine adjustment for the regulation of air entry into the lungs, the degree of washing out of CO_2 from the alveoli, and the correlation of these actions with the flow of blood through the lungs. A word may be said with regard to gas exchange in the lungs. Atmospheric air contains 20·96 per cent. of oxygen and 0·04 per cent. of CO_2. "Alveolar air," obtained at the end of the deepest expiration, is found to contain oxygen 18 per cent., and CO_2 5·6 per cent., and the rest nitrogen.

The venous blood contains about 8 per cent. of CO_2; it is not saturated with oxygen. Arterial blood, on the other hand, is saturated with oxygen and contains the same percentage of CO_2 as the alveoli—namely, 5·6 per cent. This means that the blood absorbs oxygen and becomes saturated in its passage through the lungs and gives up about 2·4 per cent. of CO_2. The latter is removed from the lungs in the tidal air and is dissipated in the atmosphere, where the percentage is so much lower; the greater the volume of CO_2 removed from the blood, the greater the volume of tidal air changed per minute.

(a) *Mechanism during Inspiration.*—Practical equilibrium is maintained between the CO_2 percentage of the alveolar air and that of the arterial blood; the level in the latter is generally, but not always, slightly higher than that in the former. The percentage both in alveoli and blood changes but little. Haldane states that "a rise of 0·2 per cent. or 1·5 mm. in the CO_2 pressure of the alveolar air and arterial blood causes an increase of about 100 per cent. in the resting alveolar ventilation."[2] Any rise of CO_2 percentage in the blood would tend to cause a change in the reaction of the blood, but for the action of buffer substances, notably the bicarbonates and phosphates. The CO_2 percentage in the arterial blood which leaves the lungs to nourish the tissues is of primary importance, because the tissue cells are intolerant of changes in reaction of the medium which nourishes them, and numerous devices are present to ensure constancy of reaction, which is, in fact, slightly on the alkaline side.

The breathing is regulated to keep the arterial percentage of CO_2 constant, and variations are met by alteration of depth rather than of rate; only after big changes is the rate altered.[3] Such alterations will, however, do no more than regulate the average percentages over several respirations. Evidence will be put forward which indicates that glottic movements greatly assist in keeping the interchange of CO_2, and hence the blood reaction, practically constant during all phases of respiration.

When inspiration commences the opening of the glottis slightly precedes the moment when expansion of the thorax and descent of the diaphragm commence; there is provided an inlet of a certain calibre in accordance with the immediate needs of the body. In some individuals the size of the glottis is not varied at each respiration, as was pointed out above. The glottis is a choked point on the air-way at all times, even when opened to its maximum extent, and therefore there is always delay in filling of the thorax, even when the force of inspiration is very gentle.

When the capacity of the thorax is enlarged air cannot enter sufficiently quickly to fill the increasing space, and there is consequently a temporary diminution of both intrathoracic and intrapulmonary pressures. When inspiration is gentle the glottis is opened to a slight degree only; the gentle force drawing in air produces a certain degree of negative pressure. When inspiration is powerful the glottis is more widely opened. But a greater volume of air is required to fill the lungs, and although the glottic inlet is wider, yet there will again be negative pressure. And if the force of inspiration be very powerful, the diminution of pressure will be greater than before.

In all cases the results of these actions are much the same; the laryngeal obstruction causes the lungs to be filled gradually instead of suddenly. As breathing is kept automatically at a fixed rate by the control of the respiratory centre, there would be the same number of inspirations every minute, whether the required volume of air entered the lungs gradually or suddenly. .The chief reason for the prolongation of air entry appears to be directed to washing out of CO_2 from the blood. The gradual entry of air during inspiration leads to gradual dilution of alveolar air, whereby the percentage of CO_2 is kept at a more or less constant level in the alveoli, and consequently in the blood. Haldane has shown that, because of the large reservoir of air always present in the lungs, the alveolar CO_2 never changes much.[3] Only about one-eighth, or perhaps rather more, of the air-content of the alveoli is changed on gentle respiration; Keith gives the figure as one-fifth.[5] The volume changed at each respiration increases on exertion; therefore the buffer provided by the reservoir of air in maintaining constancy of CO_2 is less at such times than during rest.

Even during gentle respiration there must be a content of CO_2 in the alveoli gradually tending to rise in percentage from the time when dilution with inspiratory tidal air has reached its maximum point until the next similar phase. It must be remembered that when samples of alveolar air are examined they are invariably taken at the end of the deepest expiration. The sample comes from mixed alveolar air and represents the last part of supplemental air; but it only gives an indication of the percentage of CO_2 present in the alveoli at the end of each expiration. If a sample be taken immediately after a forced inspiration results are given differing from what is found by the ordinary method. As the blood leaving the lungs will contain a CO_2 percentage almost equal to that in the alveoli, there must be some mechanism by which the percentage is kept constant; otherwise the CO_2 in the blood would gradually drop towards the end of inspiration and rise during expiration.

Maintenance of uniformity of CO_2 content of the blood seems to be dependent on the volume of blood flowing through the lungs and its relation to the air-content of the alveoli. At the beginning of inspiration the diminished intrathoracic pressure causes more blood to be drawn into the great veins and right auricle; increased intake is aided by descent of the diaphragm, which squeezes blood out of the splanchnic area. At the same time there is diminished pressure in the lungs; this causes dilatation of the pulmonary capillaries because of the lessened air pressure both in the alveoli and on the outer surface of the lungs, as Sharpey Schafer has demonstrated.[6] There is another important factor described by Lewis[7]—namely, diminution of pressure on the pericardium, as distinct from suction action on the great veins and right auricle. The heart's rate is increased among other results; this and the other effects may be shown readily by experiment.

The mean result of these various factors is that more blood is received by the right auricle, and more is pumped through the freely open capillaries. At the beginning of inspiration the air rushing into the alveoli tends to lower the CO_2 percentage; at the same time an increasingly large volume of blood rushes through the capillaries, and from it a certain volume of CO_2 is washed out. Towards the end of inspiration the dilution of CO_2 in the alveoli is at its height, and intrathoracic and intrapulmonary pressures are at the same moment at a lower level than at the beginning of inspiration. Therefore, more blood flows through the lungs and a greater total volume of CO_2 is withdrawn. The result is that the CO_2 content of the arterial blood leaving the lungs is kept constant.

That a greater volume of blood passes through the lungs during inspiration than during expiration may readily be demonstrated by Valsalva's experiment. If the changes in dilution of alveolar CO_2 described did not take place, the blood leaving the lungs during inspiration would contain a higher percentage of CO_2 than during expiration; because the alveoli would only be able to take up the same volume of CO_2 during inspiration as during expiration. And as a greater volume of CO_2 is brought to the lungs by the increased blood-flow during the former phase, there would necessarily be retention during this period.

(*b*) *During Expiration* the pressure inside and outside the lungs is raised, depending to a great extent on the position of the glottis. It is found that during expiration the glottis is narrowed to a considerable degree. As already mentioned, this sudden change in size does not occur in all subjects during quiet respiration. As gentle respiration calls for a partially closed glottis on both inspiration and expiration, the mechanism described above would still hold good.

The increased pressure on the right auricle and great veins does not permit so much blood as before to enter the heart, and the increased pressure on the pulmonary capillaries does not give so free a passage to blood-flow through the lungs as during inspiration. Therefore, the amount of blood flowing through the lungs is less during expiration than during inspiration; the volume gradually decreases from the beginning to the end of the act. As the CO_2 content of the alveoli tends to rise during expiration, there will be less washing out from the blood, especially towards the a cough causing insomnia, codeine was probably the best remedy. In the sleeplessness of uræmia, morphine was most effective and the common prejudice against its use in renal cases he considered unjustified.

2. With regard to *primary insomnia*, it was as well at the outset to make sure that the case was one of primary insomnia and not one of secondary insomnia in which some physical discomfort—such as dyspepsia, flatulence, or constipation—had been overlooked. Flatulence, either in the stomach or colon, was specially liable to prevent sleep; it was worth while, therefore, when no psychical cause for the insomnia was evident, to try the effect of an alkaline carminative draught at bed-time. In primary insomnia, one's first duty was to inquire into causes of mental discomfort. As the elucidation and removal of an anxiety state might take considerable time, the first task was to try to get the patient to adopt the right mental attitude to the symptom. As most sufferers from insomnia exaggerated in their own minds the effects of not sleeping, one should explain that there was no fear of his either dying from insomnia or of going mad as a result of it. Also, it should be pointed out that health could be maintained on a much smaller allowance of sleep than most people took and that rest and muscular relaxation were to a large extent a substitute for it. Unless the insomnia had resulted from mental overwork—and this, in the absence of coexisting worry, was a rare cause—when a holiday might effect a rapid cure, Dr. Hutchison believed it best to attempt to cure the insomnia in the environment in which it arose. Institutional treatment, however, had its advantages in cases requiring prolonged psychotherapy and, of course, in all psychoses.

With regard to drugs in the treatment of insomnia, the speaker believed it cant to say that hypnotics should only be used as a last resort and that the fear of establishing a habit was a bugbear; the possibility of the insomnia becoming a habit was a much more real danger. The removal of an anxiety state or the resolution of a conflict took time, and meanwhile, especially if the insomnia was becoming absolute, artificial sleep must be induced. As we could not afford to fail without making the patient worse, it was wise to begin with a hypnotic and dose rather more powerful than was really necessary. The bromides were, therefore, only indicated in the mildest cases; bromural and adalin were better for the less severe insomnias. Of more potent drugs, veronal or medinal (sodium-veronal) in 7½ grain doses would meet most indications. Chloral had fallen too much into disuse; it was wise to avoid it in cases of myocardial degeneration, but otherwise Dr. Hutchison believed it quite safe. Trional, from its delayed action, was specially indicated in those cases in which the patient was awake only during the latter part of the night (the so-called internocturnal insomnia). Luminal was unnecessarily powerful for use unless in exceptional circumstances, and morphine should never be given for primary insomnia outside a mental hospital.

Dr. Harry Campbell (London) defined insomnia as the "inability to enjoy a sufficiency of sleep under moderately satisfactory conditions." In the treatment of all cases of insomnia an attempt must be made to raise the level of the general health of the patient. Tranquillity of mind was essential to combat primary insomnia; the patient should endeavour to cultivate the idea that he is really going to sleep. Reading in bed, so long as it did not excite, often promoted sleep, and there were individuals who habitually read in bed until drowsiness compelled them to put out the light. Sources of irritation—cold feet, pruritus, nasal obstruction—which often interfered with sleep, should be sought for and treated. The bedroom should be dark, quiet, and well ventilated, and the bed placed away from the wall. In cases of high blood pressure the pillow should be high, but when the pressure was not supernormal and the patient was otherwise healthy, a low pillow was best. Open-air exercise was conducive to sleep and a warm bath at bed-time, with the addition of a little mustard, was often helpful. As regards climate, high altitudes were unsuitable for bad sleepers; for most patients a low altitude and a relaxing climate were preferable.

Dr. H. Devine (Portsmouth) said that in the insomnia of the acute psychoses the use of powerful sedatives which stupefied the patient and which had been described as "chemical restraint" was steadily growing into disfavour. Endeavour should be made to assist Nature to bring about a cure by careful nursing and medical treatment—attention to digestion and the state of the bowels, frequent feeding with liquid diet, &c. Direct attempts should be made to promote sleep by sponging, hot packs, or if the condition permitted, prolonged baths. Hypnotics were often necessary, but they should be used as sparingly as possible and in conjunction with such methods as described above. The aim was not to treat the insomnia itself but rather the morbid process in the organism responsible for its occurrence. The insomnia of psychoses was essentially a secondary insomnia in the sense that it was a reaction to a morbid and sensitive state of the organism. There was a practical value in regarding all cases of insomnia as the outward expression of a mal-functioning organism.

Dr. C. P. Symonds (London) dealt with certain physiological factors underlying the function of sleep. The causes of insomnia due to an increase in the flow of stimuli to the cerebral cortex had, on the physical side, been dealt with by the opener of the discussion. On the psychical side it was unpleasant emotions, such as anxiety and fear, which readily prevented sleep. He considered that the principles guiding the use of hypnotics in cases of neurosis should be (1) not to continue drugs for more than a week or so without openly reducing the dose and observing the result, and (2) never to exhibit the same hypnotic for more than three nights in succession. A habit which was valuable in some cases was that of muscular relaxation. With training, the ability to relax could be developed so that a patient might learn to relax all his limbs in turn and finally together. Dr. Symonds was doubtful regarding the wisdom of allowing patients to read or play "patience" in order to pass the time; the practice might tend towards a habit of wakefulness.

Dr. E. I. Spriggs (Ruthin Castle) considered that the insomnia of overworked business men was best relieved by advising the patient to spend one or two hours in the open air each day, or at least every other day. A regular allowance of fresh air was most important for the individual working indoors. In nervous and excitable patients, a good plan for avoiding insomnia was to persuade them to take regular rest after the mid-day meal.

Dr. D. Stone (Northampton) said that the posture adopted in bed was important. A sleepless patient—especially one with digestive trouble—should sleep on the right side, as in that position it was easier for the stomach to empty. It was not wise to go to bed on an empty stomach; a moderate meal was advisable. From personal experience in general practice, he thought paraldehyde was the best hypnotic for routine use—1 drachm was usually sufficient.

Dr. W. J. Smyth (Bournemouth) spoke of the value of hyoscine in asylum practice. In adolescents insomnia was frequently due to some anxiety or fear and was usually only remedied finally by removal of the cause. In his experience medinal was the hypnotic that gave the best results in obstinate insomnia.

Dr. W. A. Potts (Birmingham) drew attention to the value of combining hyoscine with morphine in cases in which drug treatment was necessary; the combination enabled a smaller and safer dose of each drug to be used. In certain selected cases alcohol was valuable, and even a dose of "blue pill" was often efficacious.

Dr. C. Mortlock-Brown (Braunton) pleaded for further research in the physiology of sleep and considered that hypnotics should be used only as a last resort.

Dr. Mackenzie Wallis (London) spoke of certain experiments he had carried out regarding the relative toxicity of certain hypnotics. He had found that sulphonal, veronal, and medinal (sodium-veronal) in ordinary doses had no effect whatever on the functional activity of the liver and kidneys, nor was there any effect on general metabolism. All three drugs were rapidly excreted and showed no evidence of cumulative action.

Dr. T. A. Ross (Penshurst) considered that the insomnias termed primary were in reality secondary, but that the cause was less obvious. He agreed that it was sometimes necessary to give hypnotics in cases of neurosis, but believed that the practice tended to inhibit the process of psychological investigation.

Dr. Woods Hutchinson (California, U.S.A.) said that insomnia depended upon the testimony of the patient, and the patient was usually incorrect in his statements, since no individual could testify as to how long he slept. The aim should be to try to make the patient physically fit in all respects and to persuade him to forget his insomnia.

Dr. R. Whittington (Hove) believed that the nature of the treatment adopted largely depended upon the temperament of the patient; one form of treatment might suit one individual but not another. He would have wished to hear more of hypnotism and suggestion in the treatment of insomnia.

Dr. H. Crichton-Miller (London) had found that dyspepsia was often a basis on which insomnia developed. In many cases the circulation was also at fault. He did not consider that the exhibition of hypnotics hindered a psychological investigation.

The President of the Section, in bringing the discussion to a close, said one had to think of the patient first and that experience had taught him that insomnia was often the key position to many graver conditions that might arise later. Physiologists had shown that the repair of fatigued tissue took place only during sleep. In his opinion sleeplessness should be relieved in its earliest stage—even in children. The danger of habit-formation was much exaggerated. The drug he favoured most was medinal; Dr. Mackenzie Wallis's observations constituted a good answer to the fostering of prejudice against such a sedative. He considered that if a particular hypnotic proved suitable, it was a great mistake to change it.

Friday, July 24th.

The Prophylaxis of Mental Disorder.

Sir Humphry Rolleston, in opening a discussion on this subject, stated that such a discussion, though in a special section, should be on very broad lines, for it dealt with the highest reaction of the human organism—in fact, with its reactions as a whole, whereas in other branches of medicine, one organ or system of organs chiefly attracted our attention. The public, as well as the medical profession, required education as to the way in which mental abnormalities should be regarded, and should be impressed with the commonplace that prevention was better and cheaper than cure, so that the earliest departures from the normal should at once be communicated to the doctor and remedial measures started without delay. The measures appropriate for the prevention of mental disorder were necessarily determined by the numerous forms of mental unsoundness. The multiplicity of the causes—hereditary, environmental, physical or bodily, and purely psychological—complicated the problem of prevention. Heredity and environment were closely interwoven in the causation of mental disorder as disposing and exciting factors respectively; the disease was the morbid reaction resulting from a complete set of external agents stimulating an inborn low margin of physiological resistance. The special form of nervous disorder was not inherited as such, but there was a low state of vitality. Although, generally speaking, more could be done in the way of modifying the environmental conditions—viz., by all that is included in the term "mental hygiene"—measures to counteract gross hereditary disease, such as syphilis and cretinism, must not be neglected. Half the cases of mental disorder had been ascribed to hereditary factors. As a means of prevention this factor necessarily carried with it the difficult subjects of eugenics, sterilisation of the defective, and birth control. We might wisely hesitate before advocating strict eugenic measures of breeding, which, if carried to their logical conclusion, might seriously impair the future progress of the race; for if the inborn tendency to variation, which is responsible both for mental weakness and for intellectual ability, were thus removed, a dead level of standardised men, like "Robots," might conceivably result. To a limited extent the Mental Deficiency Act (1914) had met the question of sterilisation of the mentally defective by diminishing the propagation of the handicapped child. Birth control was less drastic and difficult than the standardised propagation of the human race; it was widely practised, though far more often among those whose offspring would be of value to the race than among the very poor. The arguments against this practice were the risk of a falling population and the moral one that promiscuity would be favoured.

While fully recognising the indubitable influence of heredity, there was the opposite and more or less mechanistic conception that man's actions were determined by his response and adaptation to environmental stimuli. What was often assumed to be hereditary might really be acquired in early youth as the result of family environment and irresistible imitation. An inherited tendency might remain latent unless and until some stress was brought to bear on the individual, who then manifested symptoms of mental disorder, when an absolutely normal person would escape. The stress which was the exciting factor acted in virtue of the psychopathic predisposition, and might be: (1) Physical—trauma, infection, toxic factors, unhealthy environment, unsuitable diet; or (2) psychical—worry, emotional strain, overwork. Chronic infective foci and the resulting toxæmia, by diminishing the resistance of the body and by producing degenerative changes in the nervous and endocrine systems, constituted an important factor both in disposing to and even determining mental disorder. Auto-intoxication due to oral, tonsillar, and intestinal infection was sometimes an obvious factor. Responsible focal infections, especially disease of the accessory nasal sinuses, might remain latent and escape detection. At the New Jersey State Hospital, Trenton, the number of discharges increased from 37 to 85 per cent. after removal of oral and tonsillar infections (H. A. Cotton, 1923). The effects of alcoholism and syphilis and the means of obviating these factors were well recognised. With regard to epidemic encephalitis, more information was needed as to the prevalence of carriers and their detection, the problems of immunisation, and of specific curative treatment. A further interesting question was the possible responsibility of primary deficiency of the endocrine elements of gonads for mental disorder. Sir Frederick Mott had shown that changes in the sex glands occurred in dementia præcox, but it was difficult to disprove the view that the endocrine maldevelopment was concurrent and part of the general bodily arrest of development or precocious degeneration. Endocrine deficiency of congenital origin—e.g., cretinism—might to some extent be prevented by antenatal treatment and environmental precautions. Overpressure in schools on clever boys likely to gain scholarships was a widely recognised but somewhat neglected danger, and not infrequently led to mental sterility in later life. Precocious able boys would, of course, be in forms with boys considerably older, and therefore would be likely to share the same hours of sleep, whereas they required more on account of both their more tender years and their mental activity. Sufficient sleep and rest in the prevention of mental strain and breakdown were most important. Boys were not sent to school to earn testimonials to the transient success of a forcing system. The senseless and harmful punishment of writing out hundreds of lines and keeping boys in after school hours should be regarded as relics of barbarism.

The speaker pointed out that the possibilities included in mental hygiene were extremely numerous; they concerned the home conditions and influences bearing on young children and the education in this respect of the parents: for the impression made by environment on the young mind was of the utmost importance. Mental hygiene was the first line of defence in the prevention of mental disorder, and its want or failure was shown by the need for early treatment in psychiatric clinics, which in their turn should preserve many patients from the necessity of having to enter mental hospitals. Early treatment in psychiatric clinics attached to general hospitals had many advantages; the education of the public to the recognition that mental disorder was intimately connected with bodily disease and not a distinct and mysterious condition; from the patient's point of view the avoidance of the stigma attaching in the public mind to residence in a mental hospital and especially certification; the provision of a much more satisfactory means of educating students, not only in mental disorders, but also in the understanding of the psychological aspects of everyday practice, &c. The prevailing note in the case of early and recoverable patients should be sympathetic conciliation rather than the forbidding coercion—cheerfulness and helpfulness instead of severity and repression.

Dr. Helen Boyle (Hove) agreed that the hereditary factor was difficult to control for fear of producing a race of individuals of dead uniformity. It should be remembered that many of those who have contributed largely to the arts were mentally unstable. Also there was no definite model at which to aim—nobody had yet seen the perfect man, and perfect physical formation did not necessarily mean good mental development. As regards birth control, at present the practice was only adopted by intelligent and thrifty people, and thus those most needed tended to be exterminated. Dr. Boyle also laid great stress upon the correct upbringing of children.

Dr. Bernard Hart (London) said that cases of mental disorder could be divided into two large groups: (1) Physiogenic, which included those cases ascribed to physical causes—toxic, endocrine, heredity, and other physical factors; and (2) psychogenic—a group much subdivided and varying with the different analytical schools of Freud, Adler, and Jung. It was difficult indeed to find a single factor in the ætiology of these cases on which uniformity of opinion could be based. Consequently, in devising preventive measures great care was necessary, and our fragmentary knowledge of ætiology had to be improved. It was important to recognise that in mental disorders there were no disease-entities; what occurred was a reaction of the whole organism to its internal and external stresses; while we clung to the disease-entity idea, it was difficult to harmonise the different ætiological factors. Dr. Hart pleaded for tolerance between the different schools of psychological thought and deplored the present lack of suitable institutional accommodation for psychoneurotics.

Dr. E. Mapother (London) considered it necessary carefully to distinguish between the early treatment and the prevention of mental disorder—that is, between measures taken after the appearance of the earliest symptoms and, on the other hand, measures designed to prevent the occurrence of even first symptoms. This distinction was important because demands for public help towards early treatment could reasonably be based on moderate claims regarding our powers, while appeals in aid of prevention should be founded on our almost total ignorance of and impotence in the prophylaxis of mental disorder.

Dr. Ross said that it was most important to get medical students more interested in minor mental maladies such as the psychoneuroses. At present they were interested in physical illness only, and, in consequence, when they became practitioners and met such cases they did not know how to handle them; they either fussed over them unduly or neglected them. It was not possible for specialists or institutions to undertake the entire care and treatment of all psychoneurotics; they were too numerous and their cases were too prolonged. The patients needed support for a long time, and the bulk of this support should be given by the general practitioner.

Dr. Potts could not accept entirely the somewhat pessimistic attitude of Dr. Hart and Dr. Mapother, although he agreed that more detailed investigation and more knowledge were necessary. There was universal agreement that infections were existing factors and must be dealt with. Following this, if necessary, some form of psychotherapy should be employed. His idea was that the chief places for the prevention of mental disorder were the antenatal clinic and the nursery.

Dr. P. Watson-Williams (Bristol) dealt with the influence of toxæmia as a cause of mental disorder. He considered that by the detection and elimination of focal or other infections the occurrence of mental unsoundness could be prevented, relieved, or absolutely cured. He had seen elimination of sepsis in the nose, throat, or ear lead to the relief of neurasthenia, depression, and even delusional insanity. It was particularly latent or cryptogenic foci that were prone to cause chronic toxæmic conditions; where there is an obvious purulent discharge there was much local reaction and little tendency to toxæmia, but when the infection was associated with but little discharge, and that non-purulent or only opalescent and difficult to observe, toxæmic symptoms were more prone to arise. Hence a well-marked pyorrhœa alveolaris was less dangerous than the apical granuloma of latent dental sepsis.

Dr. Crichton-Miller agreed that the elimination of foci of infection was most important; a toxic factor might not be the entire cause, but it was the easiest to handle. He also described the blood-cell changes found in certain neuropaths.

Dr. C. A. Mortlock-Brown appeared to consider the present generation degenerate and maintained that self-control was better than birth-control. She also advocated the appointment of medical women to the Board of Control.

Dr. R. N. Craig (Torquay) gave details of two psychiatric clinics, attached to general hospitals, with which he was associated. There had been great difficulty in starting them owing to prejudice and opposition from even medical men, but the success attained by the clinics clearly showed that there was a demand for them.

The President of the Section said that over and over again he had seen mental factors neglected in patients at general hospitals; the patient was, in fact, treated in one respect (the physical) and neglected in another (the psychical). Cases of mental disorder due to toxic foci were frequently overlooked. He would deplore any attempt to eliminate the hypersensitive individual—the person who reacts quickly is often the most intellectual or the most successful in life. Unfortunately they reacted equally easily to environment and toxins. Overwork meant over-stimulation, and fatigued tissue was more likely to become infected than healthy tissue.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—In their annual report the committee of management state that it is "of vital importance that more beds should immediately be provided at the country branch," and King Edward's Fund has been asked to approve of plans for an additional 200 beds, estimated to cost at least £50,000. At the same time the out-patients' department has become "hopelessly inadequate," the attendances during the past year having exceeded 71,000. A new department, with nurses' home, resident medical officers' quarters, and workshops, will cost another £50,000, a total of £100,000, of which only £30,000 is in hand. Every branch of the work has again increased, and there is an adverse balance amounting, happily, to only £1600, as against more than treble that amount in 1923.

Reviews and Notices of Books.

HISTORY OF MEDICINE.

Proceedings of the Third International Congress of the History of Medicine. Antwerp: De Vlijt. Pp. 320. 21*s*.

THE fourth of this series of congresses has just taken place in Geneva.[1] The volume under review contains the contributions presented to the Congress which met in London in July, 1922, and was attended by some 150 delegates from 16 countries. In the epidemic section, Dr. Tricot-Royer contributes an analysis of the orders of the town council of Antwerp against plagues in the sixteenth and seventeenth centuries, and also a description of the sixteenth century leper house of Hérenthals and its documents. M. Jeanselme's paper shows the connexion of plague with the flood, famine, and earthquake which precede it, and Prof. Sir W. Simpson urges renewed attack on the problems of endemic disease in our own day. Dr. Wickersheimer gives an account of the Black Plague as it affected and was dealt with in Strasbourg in 1349, and of a "regimen" dating from this time; while Dr. R. Neveu describes the plagues of Tuscany in the fourteenth and fifteenth centuries, with an analysis of the reasons for the long-continued infections. Sir W. J. Collins gives a résumé of the work of Sir Edwin Chadwick, and Miss M. C. Buer discusses the decrease in epidemic disease in this country between 1750 and 1830, ascribing it to the improvement in medical science and popular hygiene accompanying the industrial revolution. In the anatomical section Dr. Ricardo Jorge's paper deals with the renaissance of anatomy and medicine in Portugal; MM. Laignel-Lavastine and Livet discuss the part played by symbolism in anatomy, with reference to the rules of divination, the teachings of astrological medicine, and the idea of correspondence between macrocosm and microcosm; Dr. J. G. de Lint publishes two new anatomical "flying sheets" and a fragment of an obstetric MS.; and Dr. E. T. Withington and Mr. Donald Campbell contribute papers on the anatomical writings of Galen. Prof. Ménétrier attempts to rescue the reputation of anatomists by citing instances of their humanity toward "subjects" handed over to them imperfectly executed and susceptible of restoration to life. Dr. V. H. Turkomian discusses the knowledge of anatomy possessed by the ancient Armenians, and also shows that that country was a pioneer centre for propagation of the practice of inoculation for small-pox. M. Fosseyeux's paper describes the anatomical studies of Déscartes, and MM. M. Villaret and F. Moutier discuss plagiarism in anatomical illustrations during the sixteenth century. Dr. K. Lander deals with the anatomical studies of women before the nineteenth century. Mr. T. W. Parry describes prehistoric trephination in Great Britain. In the pharmacy section Dr. M. A. Van Andel describes the history of human fat as a medicament, and Dr. Van Schevensteen the use of remedies taken from the human body in the treatment of eye diseases. Dr. P. Dorveaux contributes a study of the seventeenth-century apothecary, Le Febvre Nicaise, and Mr. J. P. Gilmour sketches the history of pharmacy in the British Isles. M. C. H. Fialon outlines the statutes of the Master Apothecaries' Corporation of Lyons, and Mr. C. J. S. Thompson gives the history of Hiera Picra. In the veterinary section M. M. Sevilla writes on the "colic" syndrome in the Græco-Roman epoch, Major-General Sir F. Smith publishes an abstract of his paper on English veterinary anatomy from the sixteenth to the eighteenth centuries, and Mr. F. Bullock an abstract of his account of the fifteenth century MS. "Mulomedicina Chironis." M. L. Moulé describes the conditions grouped by ancient writers under the term "Malleus." Among miscellaneous papers are found one by Dr. F. G. Poynton on the early aeronautical work of medical men; a study of Byzantine culinary recipes and ingredients by MM. Jeanselme and Oeconomos; and an account of the use of the Danish amulet "Muskatnuss," by Mr. J. W. S. Johnsson. Of particular interest at the present moment is a description of the psychiatric ideas of Roman jurists by Dr. S. K. Waard. MM. Laignel-Lavastine and J. Vinchon contribute an account of the psychiatric work of Jean Schenck, and M. Jeanselme attributes the degeneration of the Carolingian family to hereditary neuropathic taints. Dr. N. G. Horner presents an amusing seventeenth century journal or daybook which belonged to Dr. John Westover, of Wedmore. Among the portraits published are one of Luis Mercado, physician to the Spanish court in the sixteenth century, and that of a young man, by Moroni, showing an apparatus for drop-foot. Of literary interest are Dr. J. Van Gils's comparison of the doctors of Molière with those delineated by Shaw, and a note by Dr. H. Leclerc on the reference to the "sacred thistle" in *Much Ado About Nothing*. Newly published texts include the preface of a thirteenth century Latin edition of the sixth book of "Epidemics" (Mrs. Singer), an Italian MS. giving a large number of hitherto unknown names of Salernitan doctors (Dr. P. Capparoni), and a treatise on air and winds published in 1612 by Panarolo (Dr. G. Hinsdale). The collection concludes with a paper by Mme. Panayotatou on hygiene and dancing among the ancient Greeks.

The volume may be cordially recommended to those who have a taste for medico-historical hors d'œuvres.

HANDBUCH DER TROPENKRANKHEITEN.

Third edition. Vol. II. By various Authors. Prof. Dr. CARL MENSE, General Editor. Leipzig: Verlag von Johann Ambrosius Barth. 1924. With 306 text figures, 4 black and white and 14 coloured plates. Pp 1019. G.M. 66–70.

THE second part of the new "Mense" is a ponderous volume comprising a vast amount of information upon a great variety of essential tropical diseases and subsidiary subjects. As has been customary in previous editions, the bibliography is remarkably complete. But the most important diseases do not appear to be arranged in any logical order; thus we have leprosy, undulant fever, cholera, psittacosis, plague, tsutsugamushi disease, sprue, beri-beri, tropical skin diseases, and those caused by tropical poisons, both of vegetal and animal origin, treated in sequence—a lack of method detracting from the real merits of the work.

The chapter on leprosy by Dr. Georg Sticker, of some 120 pages, includes a history of the disease from the earliest times and is a definite contribution to medical literature. Interesting statistics are given of the present-day distribution of leprosy; in China and the East Indies there are 50 lepers to every 100,000 inhabitants; in Finland, 2; in Egypt, 20; while in the Marquesas islands there are known to be 250 amongst a total of 4000 inhabitants. Dr. Martin Mayer is responsible for a succinct and well-written chapter on undulant fever. In the treatment of this particularly intractable fever attention is directed to the injection of colloidal metals, notably collargol. Cholera, from the pen of Dr. Paul Krause, is mainly remarkable for the chronological table of various cholera epidemics from the year 1817 onwards; the information being wholly derived from Russia from 1914 up to the present time. The various methods of treatment which have from time to time been advocated are given in detail, but no particular line is specially advocated, while the injection of hypertonic salines receives but scanty recognition. Dr. Filippo Rho writes on psittacosis, though it is by no means clear why this somewhat exceptional disease should be included in a treatise on tropical medicine. The article on plague is by Dr. P. C. Flu, of Leyden, and contains a careful description of the bacteriology of the disease, while the attention given to morphology of the various plague-disseminating fleas is noteworthy.

---

[1] THE LANCET, 1925, ii., 291.

Tsutsugamushi disease, *or Japanese river fever*, by Dr. M. Miyajima, comes from an authoritative source and is welcome on account of its comparative brevity and the excellence of the illustrations. The story of sprue, by Dr. Hermann Dold, occupies a great deal of space, of which the greater part is taken up by a detailed account of the pathological anatomy. The recital of many pathological items which apparently have no bearing upon the ætiology of the disease renders this section confused and inconclusive. Beri-beri, by Dr. Bernhard Nocht, is an extremely good account of the symptomatology and treatment of this peripheral neuritis; the whole subject of vitamins receiving adequate consideration. Tropical skin diseases, including oriental sore, ainhum, climatic bubo, veldt sore, ulcerating granuloma, and other less well-defined conditions are described by Drs. A. Plehn and Karl Mense, jun. We note that yaws and syphilis in the tropics, illustrated by some characteristic photographs, are also included in this section, though more generally regarded by other writers as being systemic in nature with cutaneous manifestations. The same authors are responsible for mycetoma, tinea umbricata, sporotrichosis, and other fungus diseases.

Poisonous symptoms due to tropical plant poisons are thoroughly discussed by Dr. Rho. Originality and thoroughness of this section make it the most striking contribution in the present volume. Dr. E. S. Faust deals with the analogous conditions produced by animal poisons, including snakes, fishes, reptiles, arthropods, and mollusca.

The general printing and reproduction of the illustrations are, on the whole, good.

An Index of Treatment.

By Various Writers. Ninth edition. Edited by Robert Hutchison, M.D., F.R.C.P., and James Sherren, C.B.E., F.R.C.S. Bristol: John Wright and Sons, Ltd. 1925. Pp. 1035. 42s.

After an interval of less than four years the ninth edition of this well-known manual of treatment has been produced. Recent additions to therapeutical knowledge have rendered its issue advisable sooner than was anticipated. Two subjects hitherto omitted appear for the first time—namely, Infective Endocarditis (Sir Thomas Horder) and Spinal Analgesia (Dr. Felix Rood), while additions have been made to the article dealing with the general treatment of tuberculosis. The article on diabetes by Dr. Edmund Spriggs has been rewritten in the light of modern research, but we are glad to say that the same amount of space, or more, is still devoted to the informing tabular statements with regard to the composition and value of different foods and their arrangement for the various meals. It will be noticed that the article on asthma has been excellently brought up to date, and other sections which have received notable additions are those dealing with venereal and tropical diseases.

In its latest issue the Index of Treatment can be recommended, in accordance with previous notices, as a first-class book of reference.

International Clinics.

A Quarterly of Illustrated Clinical Lectures and Articles. Vol. II. Thirty-fifth series. London: J. B. Lippincott Company. 1925. Pp. 311. Per set of four volumes, 50s.

This, the latest issue of a quarterly symposium of lectures and articles on medicine, surgery, and obstetrics contains, like its predecessors, many interesting sections contributed by well-known authorities. Among the contents of this volume which are especially noticeable may be mentioned a dissertation on the present status of affections of the kidney by Dr. I. W. Held of New York; a paper on cystic neoplasms of the ascending mesocolon by Dr. C. G. Cumston of Geneva, in which the symptoms are well set out and the diagnosis discussed; and a suggestive essay by Dr. J. J. Walsh of New York entitled "The Patient or His Disease." Throughout this last paper the valuable advice is insisted on to observe the patient's mental attitude towards his own complaint; it is pleasant to note in this connexion a reference to a paper read before the Charaka Club in New York by Dr. Frederick Peterson, which dealt with the neuroses brought out among those who served in the American Civil War. It is clear from this paper that the experiences of more recent date were not without precedent in America, though the conditions of warfare were so different.

Clinical Laboratory Methods.

Second edition. By Russell Landram Haden, M.A., M.D., Professor of Experimental Medicine, School of Medicine, Kansas City. London: *Henry Kimpton. Pp. 310. 18s.*

This book differs from most of the myriad others which have appeared in the last decade under closely similar titles in that theoretical and clinical considerations have been almost entirely eliminated; this has made possible the inclusion of a great deal of purely technical matter which must otherwise have been omitted from a volume of this handy size; and, while reducing its appeal to the student and general practitioner, very considerably enhances its value to the whole-time laboratory worker. The section devoted to biochemical procedures is by far the best; the author has limited himself to describing one technique only for each of the procedures included; his choice has not always fallen upon the particular one most popular in this country; in fact, as was more or less inevitable, it has usually failed to do so. In every case, however, the methods described are sound and well approved, and the descriptions of them are clear and accurate. Very valuable chapters are those on the use of the colorimeter and on the standardisation of quantitative reagents. The bacteriological section is of less value to English readers, and most of the illustrations are familiar.

The Essentials of Healthy Living.

By William S. Sadler, M.D., F.A.C.S., formerly Professor at the Post-Graduate Medical School of Chicago. New York: The Macmillan Company. 1925. Pp. 481. 15s.

This appears to be at least the fourteenth book on health matters written by Dr. Sadler for the lay public as his contribution to the educational campaign now proceeding in America and other civilised countries for creating an "urge for health," as it has been called. As Prof. W. A. Evans says in an introduction, "health cannot be greatly improved from above downwards," and he quotes the baffling hopelessness of trying to improve the health of ignorant natives in tropical countries. Dr. Sadler believes that "personal hygiene is the keynote to the health teaching of the coming generation," and this book is a veritable text-book on the art of keeping healthy. It is a long way from the primitive poster with "Kill that fly" written upon it in large capitals to a volume of nearly 500 pages, but if only the intelligent section of the community, or at any rate those that can afford a guide to health at the price of this volume, can be "won for health," the movement will slowly spread downwards. Some of the chapters here strike an original note, particularly that on the history of preventive medicine with which the book opens, and one on "The Mission of Pain" which is full of common-sense teaching. The remainder of the volume deals along the usual lines with the different systemic diseases, diseases of various organs, and matters of general hygienic interest.

Symptoms of Visceral Disease.

Third edition. By Francis Marion Pottenger, A.M., M.D., LL.D., Medical Director, Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, California. London: Henry Kimpton. 1925. Pp. 304. 28*s.*

This is the third edition of a book which the author in his preface states to cover a unique field in clinical medicine, the uniqueness, we believe, being to make the patient the chief object of study. We confess that we are still puzzled, as we were in previous readings of this suggestive book, to understand in what this claim to particular singularity consists. In general arrangement the book remains as before—that is, an introduction being followed by three parts entitled (1) Vegetative Nervous System; (2) Relationship between this System and Visceral Systems; and (3) the Innervation of Important Viscera and a Clinical Study of the Germane Reflexes. The reflections are often sound and sometimes obvious, and the work is beautifully illustrated.

A Manual of Pharmacology.

Sixth edition. By Walter E. Dixon, M.A., M.D., F.R.S., sometime Professor of Materia Medica and Pharmacology at King's College, London. London: Edward Arnold and Co. 1925. Pp. 478. 18*s.*

We are glad to receive a new edition of this admirable manual. It has been completely revised in conformity with recent knowledge by Prof. E. Mellanby, Dr. O. Inchley, and Dr. A. J. Copeland, and additions are included covering all accepted knowledge on the subject of pharmacology. The information is imparted in a form useful alike to the student of pharmacy and of medicine.

We have noted before the essentially practical nature of the work, which is at the same time an exposition of the relations between physiology and medicine. Looking back on the way in which pharmacology was taught as recently as 25 years ago, we can see how the large and varied researches in physics and chemistry which have taken place in the interval have enabled teaching to assume the logical character which Prof. Dixon and his collaborators give to it. The reader, for example, of Chapter XVII. in this book, which deals with the drugs acting locally on the alimentary canal, will obtain arguments for therapeutic procedures which he may have to undertake daily in the course of practice. He will know both what to do and why he should do it, and throughout the volume consultation will put him in the same position along other lines. The manual is in the first rank of books available on its subject.

Scientific Preservation of Food.

By Thomas M. Rector, Consulting Chemist. London: Chapman and Hall, Ltd. 1925. Pp. 213. 10*s.*

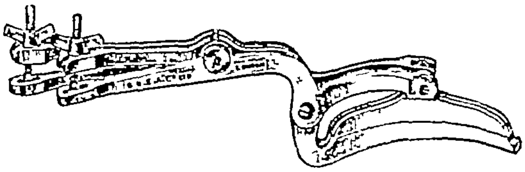
It is not very evident for whom this book is intended. It gives a clear, but rather gossipy, account, freed from technicalities, of the different methods for the preservation of foods. Indeed, technicalities are so eliminated that the book will make but little appeal to the chemist, bacteriologist, or medical expert interested in the scientific data underlying the problems of food spoilage and their prevention. But to the medical man who wishes to obtain a broad general idea of the methods employed in food preservation, this book may make appeal, and it will be found of considerable interest to laymen. It is, however, a serious defect in a book issued in 1925 that the important subject of vitamins and the extent to which they are destroyed or damaged by food preservation methods is entirely ignored. Vitamins, indeed, are only incidentally mentioned. In other directions words with a technical meaning are used without adequate explanation, a defect if the work is intended for the uninitiated.

In scope the work is comprehensive and includes short accounts of the nature of the main types of manufactured and preserved foods. The causes of food spoilage are discussed, including those from insects and larger animals, micro-organisms, enzyme action, and physical and chemical conditions. The food preservation methods include simple storage, application of cold, dehydration, chemical preservation, preservation by fermentation, hermetically sealing, heat sterilisation, and pasteurisation. In the description of these processes the author follows customary lines, but here and there unusual pieces of information are quoted. For instance, it is mentioned that the United States Bureau of Fisheries during the war recommended the canning of dog-fish and other members of the shark family under the name of "grey-fish." When acted upon by many canners it was discovered that the flesh of sharks contained urea which decomposed in time to ammonia, spoiling the flavour of the product and swelling the container. This caused great loss to canners and illustrates well the importance of scientific knowledge in relation to food preservation.

New Inventions.

A NEW GASTRECTOMY CLAMP.

Surgeons who have had practical experience of the modification of the Billroth I. gastrectomy operation introduced by Schoemaker of The Hague[1] will have found considerable difficulty in applying Schoemaker's crushing clamp to the stomach in certain cases. That instrument has to be passed across the stomach from the greater curvature, and where the ulcer is high on the lesser curvature, or the stomach not very mobile, it is sometimes impossible to apply the clamp sufficiently above the lesion. The clamp here illustrated is designed to extend the range of this ingenious and physiologically admirable operation. It is applied from the upper border or lesser curvature of the stomach, with the inner and outer halves clamped together by the central milled screw and by an interlocking device at the tip of the blades. The two upper blades are set on a rocking joint so as to secure even crushing of the stomach, and the upper and lower blades are so ground as to fit into each other without risk of side-slipping or shearing the stomach wall. The crushing is effected by tightening the wing nuts on the ends of the handles. When the distal portion of the stomach has been cut away, exactly as in the Schoemaker operation, the outer blade is removed by simply releasing its wing nut and the central milled screw. I have found that this instrument simplifies the Schoemaker operation considerably.



I am indebted to Dr. K. B. Pinson, anæsthetist to the Manchester Royal Infirmary, for designing it, and it has been made for me by the General Radiological and Surgical Apparatus Co., Ltd., 204–6, Great Portland-street, London, W. 1.

John Morley, Ch.M. Manch., F.R.C.S. Eng.

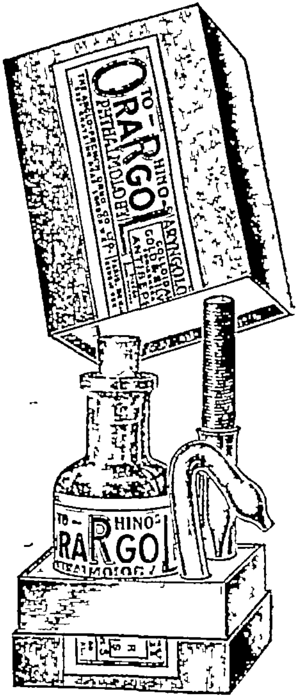
ORARGOL

(A.F.D.)

An electrically prepared suspension of

Colloidal Gold & Silver.

Indicated in the same diseases as colloid silver, Orargol has a superior action because of the addition of the powerfully anti-infectious colloidal gold.

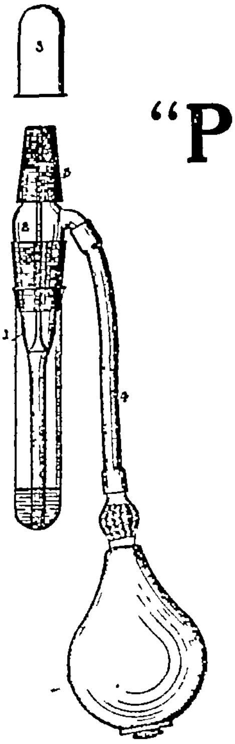


FORMS & INDICATIONS:—

ORARGOL OUTFIT (as illustrated)
OTO-RHINO-LARYNGOLOGY.

ORARGOL AMPOULES 5 c.c. & 10 c.c.
ACUTE & CHRONIC INFECTIOUS CONDITIONS.
(Septicemia, pneumonia, influenza, etc.)

ORARGOL (in bulk)
INTERNAL & EXTERNAL ANTISEPSIS.
(Intestinal intoxication, wounds, etc.)



"Pharmasol" Nose Spray

A small spray specially made for nasal treatment with colloidal solutions (Orargol, Pharmasol Argentum, etc.).

EASILY STERILISED.

THE TREATMENT OF FRACTURES.

The important series of lectures by Sir William de Courcy Wheeler which has been appearing in our recent issues and terminates to-day, and the discussion on the subject at the meeting of the British Medical Association at Bath, have combined to awaken a widespread interest in the treatment of fractures, and especially in that treatment as carried out in our great hospitals and as taught to our students. That this treatment might be greatly improved no surgeon will deny, but as to how it should be improved opinions differ, and, broadly speaking, there are three schools of thought. First, there are those who would retain the present system of treatment in general wards by general surgeons; secondly, those who would treat these cases in a special department under general surgeons; and thirdly, those who advocate a department controlled by specialists. The first school claims that specialisation has already gone too far; that it is to the great general surgeons of the past that we owe most of our knowledge of fractures; and that, from the point of view of the student, the removal of these cases to a separate department would withdraw them entirely from his range of educational subjects—for no one would be found to suggest that intensive attention to fractures should form another special subject in the ordinary curriculum. The second school would seem to find a happy mean and to be in a very strong position, were it not that the third maintains that the general surgeons would never go near the fracture department, and that in any case the average general surgeon, despite his position on the hospital staff, often knows little specially about fractures or their treatment. And there is occasionally just enough truth in this final argument to give very serious point to their contention.

The matter might be left to academic discussion, when we can see directions in which entertaining debates would ensue, were it not that it is in reality one of the most serious problems of practical surgery at the present day. With the increase of machinery and of mechanical transport and the general speeding up of life the number of fractures has enormously increased. Their occurrence forms a serious item in the industrial problems of to-day, and, quite apart from individual considerations, their mismanagement may be a source of serious loss to the community. The vast majority of these cases will of necessity come to be treated neither by fracture specialists nor by general surgeons at hospitals, but by general practitioners who have so wide a range of professional and scientific duties that they can only pursue routine of the proper standard. The careful segregation of a few of these cases of fracture into special departments at the great teaching hospitals would certainly raise in a proportional number of centres the level of routine, but such sporadic instruction would be a mere drop in the ocean of real need—namely, that our students in the mass should receive better instruction in the treatment of fractures. It is undeniably the case that the student cannot be well taught on cases which are badly treated, while at the present time the treatment of fractures in general surgical wards is often left entirely to the house surgeon, who cannot possibly have the knowledge required to do the best for the case, and whose unfailing enthusiasm will not supply the experience wanted. The present system, indeed, when closely examined, has practically nothing to commend it, for it is often unfair alike to the patient and to the student, whilst it is not unusual for a hospital surgeon, whose interest is attracted to other branches of surgery, to regard the fractures in his beds as mere encumbrances of the ground at his therapeutic disposal. A far better arrangement, and one likely to meet the reasonable requirements of all concerned, would be the setting aside of special wards for the treatment of fractures, to which the patients would be admitted under the charge of the various surgeons on the staff, but ensuring that these wards should be under the charge of a senior medical officer of the standing of a registrar, with an aptitude for the special work. The house surgeons of the different members of the staffs would look after the cases of their respective chiefs as they do at present, but their work would be carried on under the eye of this senior medical officer, to whose advice they would be expected to defer. The members of the staff really interested in the treatment of fractures would have the inestimable advantage of the assistance of an expert, whilst the student would be presented with an object-lesson in systematic treatment which he would be scarcely likely to forget. All the experience of the war in the treatment of fractures went to show how much better this was carried out when the cases were grouped together in one ward and under one control, and far from nursing being more difficult under these conditions, it became easier from the systematic arrangements which could be made for its requirements.

We think that these are the sound lines on which to employ and develop specialism in any important or more or less general branch of medicine, especially in those hospitals which are responsible for the training of our medical students. At the present time the student may be too much at the mercy of men of high scientific attainment, each of them convinced that his own is the only subject that matters. They may load him up with knowledge which would be worth its weight in gold if he could use it, but to him it is heavier than lead and just about as useful; and thus his frail barque, blown from one department to another, is finally wrecked by a brutal examiner who asks him practical questions. The fact that so many of our students succeed in arriving at port, and later in becoming really useful and practical men, says more for their power of endurance than for the wisdom of their educational training in many schools, though there are teachers in those schools whose devotion minimises the difficulties. It is undoubtedly to the specialist, willing to devote his energies to a limited field, that surgery owes some of its greatest advances, but it is from the teaching of the general clinician, the man who speaks from a wide experience spread over many branches of his art, that the student will learn the principles upon which he will ultimately rely. It is, we think, a matter for real regret that many surgeons have become specially engrossed in other branches so as to lose sight of the importance of fractures, leaving their treatment to be carried out along unprogressive and uninspiring lines. Why this should be we cannot guess, for not only are the highest skill and ingenuity called for in the modern and special methods of this branch of surgery, but the cases requiring aid are increasing, and the general practitioner will need more assistance than he now gets from his training. Some such plan as we have suggested might help the student towards practical skill in a vital subject, and might bring back to the hospital surgeon a true sense of proportion and an appreciation of the exquisite art of which British surgeons were once justly proud.

◆

FOOT-AND-MOUTH DISEASE.

AFTER the two abortive attempts which have been made to elucidate the mysteries of foot-and-mouth disease by appointing committees to make investigations, it is most encouraging to find that the third council, constituted as recently as March, 1924, under the presidency of Sir CHARLES SHERRINGTON, and later Sir WILLIAM LEISHMAN, is already in a position to issue a report[1] which sets out solid and substantial progress. The work has been done partly at the laboratories of the Ministry of Agriculture at Weybridge under the supervision of Sir STEWART STOCKMAN, and partly at the Lister Institute under Dr. J. A. ARKWRIGHT, who had experience of the disease in the ill-conceived attempt to work at it on a hulk in the Thames estuary. So far their observations have been confined to small laboratory animals, but by the adaptation of the Ministry's cattle testing station at Pirbright an admirable establishment has been secured where good facilities for exact work can be combined with a reasonable degree of isolation and experiments on pigs and cattle can be begun. This postponement of the direct attack on the disease in farm animals has not been without its advantages, since it has enabled attention to be concentrated on the means available for the identification of the virus and on its nature and properties, necessary preliminaries to the investigation of the main problems which are the mode of spread and the possibilities of protective inoculation.

It is curious that LÖFFLER and FROSCH, who found as long ago as 1897 that the vesicular fluid remained infective after it had been passed through a Berkefeld filter, failed to reproduce the disease in the small laboratory animals, for recent workers have all agreed that the guinea-pig may be infected with a regularity and certainty and with resultant lesions so characteristic that it is of the greatest value as a test animal. Almost any sort of inoculation gives positive results, but infection is best achieved by intracutaneous injection into the skin of the pad of the hind foot. After an incubation period of one to four days, redness and swelling appear at the site followed quickly by vesiculation. One or two days later symptoms of generalised infection appear; the animal is obviously ill, loses weight, there is often diarrhœa, and blisters appear in and about the mouth and on the fore-feet; appropriate experiments show that the virus is present throughout the body, mainly in the blood. As in cattle the mortality is low—about 5 per cent.—and the recovered animals are highly resistant to a second inoculation. This guinea-pig reaction is the only practicable means at present available for identifying the virus. A rather limited series of experiments on other animals indicates that a proportion of white and wild brown rats can be infected with some difficulty and the long-tailed field mouse seems to be quite susceptible; with house mice, white mice, and fowls the results were negative. Attempts to transmit the disease by bugs failed, and epidemiologically it is very remarkable that infection is never transmitted from diseased to healthy guinea-pigs living together.

Using the guinea-pig reaction, most interesting observations have been made on the nature of the virus. It is present in abundance in the fluid of the vesicles, about 0·05 c.cm. of a 1 in 1,000,000 dilution being regularly infective. It dies in a day or two at 37° C., in the cold it survives for months, and if diluted vesicle fluid is rapidly dried over sulphuric acid it may remain potent for at least six weeks; infected tissues can be conveniently preserved in 50 per cent. glycerine, especially in the cold. As is well established, the virus readily passes through porcelain filters, and it is so small (or of such an abnormal gravity) that it cannot be concentrated by centrifugalisation; when in blood serum it is not entangled in the precipitates formed by precipitins or in the general coagulation of the proteids brought about by 60 per cent. alcohol. Nor are its dimensions or its substance of the nature which leads to its absorption onto the surface of particles such as red blood corpuscles, dead bacteria, or kaolin. Its resistance to ordinary killing agents is equally remarkable. In 60 per cent. alcohol it survives for 18 hours at room temperature, whereas *B. coli* and staphylococci are killed in a minute; in 0·5 per cent. phenol it lives for 21 days, and for two days in a saturated solution of chloroform in water; ether vapour does not kill in 36 hours, though 1 per cent. antiformin destroys it in an hour. Attempts to repeat the cultivation on artificial media reported by FROSCH and DAHMEN last year have failed even after a personal visit to Berlin, where Dr. ARKWRIGHT and Dr. S. P. BEDSON were freely shown the methods used by those workers. Such seems a common fate of much-advertised discoveries. The progressive transmission of the disease through guinea-pigs without loss of virulence seems then to be the only evidence that the virus is alive. Its other properties do not correspond with any recognised conception of living matter, nor is there at present any proof that it is particulate. It may, indeed, be a real *contagium fluidum* at last, and these researches are at least as important from this point of view as they may be as a beginning of gaining control over a disease which has been an intense agricultural nuisance for long enough.

◆

THE PUBLIC HEALTH ACT, 1925.

THE Minister of Health has published a summary of the new Public Health Act which came into force on Sept. 8th.[1] The Act covers a wide range and much enlarges the powers of local authorities, though many of its provisions require adoption by the local councils before they come into force. They deal with many matters of housing, drainage, recreation grounds, and street planning, as well as with more strictly medical matters. The section on verminous premises, &c., enables the local authority, on a certificate of the medical officer of health or sanitary inspector, to cause verminous articles in any premises used for human habitation to be cleansed or destroyed at the public expense. The owner or occupier of verminous premises may be required to remove the wallpaper or take any other steps necessary for clearing the vermin. Any person notified as being in a verminous condition may be removed by his own consent to a cleansing station, or if he does not consent a petty sessional court may order his removal for cleansing. Women are to be treated only by a medical practitioner or a woman authorised by the M.O.H. The section dealing with infectious diseases provides a penalty not exceeding £5 for any person in whose dwelling a patient has died of such a disease if the owner of the dwelling fails to take reasonable steps to prevent persons coming into contact with the body. It enables a justice to grant the M.O.H. a warrant to enter a common lodging-house and examine its inmates if the existence of such disease is suspected; or the lodging-house may be closed by the petty sessions. The diseases included in the term "dangerous infectious disease" are those listed in the Notification Act of 1880. The list, therefore, does not include plague, cerebro-spinal fever, or dysentery, but it may be added to by the Minister at need. County councils and urban authorities are enabled by this Act to apply to a court of summary jurisdiction for an order for the removal to hospital of any person suffering from an infectious pulmonary tuberculosis and for his detention up to three months, even contrary to his wish. To safeguard the patient in such a case it is enacted that this power shall only apply where the accommodation prevents the adoption of adequate measures against the spread of infection and where it can be shown that there is serious risk to others. The period of detention may be extended a further three months if the circumstances are unaltered. Section 67 provides that any local authority may arrange for the publication of information on health questions and for lectures and display of pictures. Section 72 forbids the sale, preparation, or storage of foodstuffs in any room where a w.c. or sleeping place communicates directly or where there is inlet or opening from any drain. Dealers in rags and bones are not to be allowed to sell food or toys of any sort. The Act does not apply to London except in its ninth section, dealing with baths and washhouses. This part removes the statutory prohibition on mixed bathing. The amendments thus effected in the law are a preliminary step towards the much-needed consolidation of the Public Health Acts into a reasonable code.

TUBERCULOUS MILK: NEW REGULATIONS TO PREVENT HUMAN INFECTION.—The Minister of Health has introduced new regulations (H.M. Stationery Office. 1925. 1d.) investing local authorities with specific powers for the purpose of preventing the spread of infection by tuberculous persons handling milk. The enforcement of the regulations will be a matter for the local sanitary authorities; they forbid any person suffering from tuberculosis of the respiratory tract to enter on any employment or occupation which would involve the milking of cows, handling of vessels used for milk or the treatment of milk. Any such person can be required to discontinue his employment at a week's notice, with right of appeal to the courts. The new regulations to some extent remove the restrictions imposed on local authorities in cases of notified tuberculosis. Authorities are urged, however, to make every effort to preserve the confidential character of notifications as far as is consistent with the due exercise of the new regulations. The medical officer of health is required to take all reasonable steps, including expert clinical and bacteriological examination, to be sure that the suspected person is really suffering from tuberculosis.

Annotations.

"Ne quid nimis."

VOCATIONAL TESTS.

THE familiar question "What shall we make of the boy?" has usually been settled in the past by family conclave, modified by financial considerations, the desire of the father either for a successor in his business or to see his son succeed in some line of life where he himself has failed and, to an increasing extent in recent times, by the expressed wish of the child himself. In the near future it is not so certain that any of those factors will have a place in the selection of a career. The psychological expert will be called in to settle the matter by the standardised tests that are already being used extensively in America and on the continent. In Germany, for instance, such firms as Osram, A.E.G., Siemens, Krupps, and the Post Office and State railways have established psychological laboratories in which their new employees are tested before being allocated to the various branches of the firm's activities. Several large firms in this country also have sought the aid of the National Institute of Industrial Psychology in instituting definite psychological tests. A committee of the British Association under the chairmanship of Dr. C. S. Myers drew up a report for presentation to the Psychological Section at Southampton. The report reviews the present position of vocational testing and asks for a grant towards the expenses of a systematised research into the subject. The committee say that:—

"In order to define the position of psychological tests in schemes of vocational guidance and selection it is important to realise that the school records give only one side of a child's mental or physical activities. The records are obtained under conditions very different from those obtaining in the outside world, and their value must be estimated accordingly. In the same way a teacher's estimate of a child's ability is only valid within his sphere of observation; similarly with the estimates of parents and guardians. The medical examination can give help mainly in determining for what occupations a child is not fitted. In this sphere there is an enormous ground to be covered before valid positive information can be obtained. Psychology can help in forming a truer estimate of the value of the children's own wishes and inclinations in determining a choice of occupations, and it can survey more completely and exactly than any other method the child's mental and physical activities. Psychological tests can be applied which will ascertain, for instance, his level of intelligence, measure his manual dexterity, and to a certain extent estimate his temperamental qualities. This information is, however, of little use unless the extent to which these qualities are required in everyday occupations has also been determined, and this implies a careful analysis of the requirements of the occupations and a classification of those requiring allied ability. When such information is available reliable advice can be given.

"With the rapid development in this work that has taken place during the last few years, there has arisen a demand for persons who have received training in the methods of devising, applying, and evaluating suitable tests, and a number of bureaus have organised training courses for those who wish to take up this work. In nearly every country of the world the work of developing vocational tests is proceeding rapidly, and it is felt that in order that workers in this country may keep abreast of the developments here and abroad, full information should be available concerning: (1) vocational tests that have proved of value in practical use; (2) research work that has a direct bearing on the development of vocational tests. In order to do this satisfactorily it will be necessary to get in direct touch with all organisations carrying out this work and to obtain, wherever possible, copies of the tests, accurate descriptions, drawings, and illustrations of apparatus used, &c."

There can be no doubt of the value of such research. Those who believe that the true vocation of the best type of worker is indeed "a call," strong enough to drive the individual to his destiny over all obstacles, must nevertheless admit that to many men such an experience comes late if at all, and any laboratory process that can reduce the number of square pegs fitting clumsily into round holes is bound to increase the well-being of the community as well as the sum total of individual content.

THE NEW CENTRAL PHARMACOLOGICAL LABORATORIES.

THE plan to establish new pharmacological laboratories at the headquarters of the Pharmaceutical Society[1] has reached the stage at which a director is being sought, and in all probability the laboratories will be fully equipped and staffed before the Therapeutic Substances Act comes into operation. The detailed arrangements and the lines on which the scheme will develop will not be determined until the director has been appointed, but we understand that it is the intention of the Pharmaceutical Society that commercial testing as well as research work in pharmacology shall be commenced at the earliest convenient time. The director will be given a free hand in the choice of equipment and in the selection of his staff, and while the whole of the work of the laboratories will be under the supervision of the director the routine commercial testing will be left as far as possible in the hands of competent assistants, freeing the director to carry out researches. We have inspected the four laboratories that will be placed at the disposal of the director, and this accommodation would appear to be sufficient for some time to come, but if the work develops to the extent that is hoped it may be necessary, in due course, to provide further premises. It is probable that in the earlier period the work will be confined to the physiological standardisation of drugs such as digitalis, strophanthus, and ergot, these being typical examples of drugs which cannot be standardised by chemical means, and that the standardisation of vaccines and sera and similar substances will be deferred until a later period in the development of the scheme. This, however, is a matter for future decision. Commercial testing for firms which are not in a position to undertake the testing of the products which the Therapeutic Substances Act will require to be standardised is not likely to cover the cost of the laboratories, and indeed it is not intended that the laboratories should be self-supporting. The advisory committee, which includes Sir Nestor Tirard, Dr. H. H. Dale, and Sir Humphry Rolleston, will assist the Council of the Pharmaceutical Society in selecting the director.

THE DENTAL SERVICE IN THE U.S. NAVY.

THAT the care of the teeth of the men of the U.S. Navy obtains, and rightly, grave consideration from the officers of the Medical Corps, is evidenced by the issue of a " Dental Number " of the *U.S. Naval Medical Bulletin* (for April). The Surgeon-General, in his recent annual report, observed that there is now in actual service one dental officer to every thousand men, but that the establishment, if attained, would provide one officer to 615 men, although, in his opinion, there should be one for each five hundred. The actual work of officers of the Dental Corps is much lightened by the help given by the naval dental assistants or dental technicians (selected from the sick-berth staff and trained specially for 16 weeks), who act as "oral hygienists"; they clean mouths, do scaling, and give patients individual teaching besides assisting the dental officer in the management of apparatus, the sterilising of instruments, and so forth. The importance of the work done at naval training stations, where recruits are received, is shown by the experiences reported from one of them, where, of 4337 recruits examined and charted in six months, 3016 were found to require treatment; 1246 teeth were extracted, 6314 cavities found, and 1040 fillings done, while 5274 fillings were left over to be carried out in rotation on board ship. A dental ward of 12 beds has been opened in the naval hospital at Norfolk, Virginia, with complete annexes for dental work. It is there recognised that the dental officer's first duty is that of "prophylactodontist," especially before operations requiring general anæsthesia, and in syphilis. His next care is the elimination of dental focal infections, which may lead to systemic sequelæ, such as rheumatism, gastro-intestinal disorders, diseases of eye, ear, nose, antrum, and skin. Lieut.-Commander J. R. Barber, Dental Corps, U.S.N., has devised a scheme of routine for the dental examination and treatment of the men of small craft arriving at the New York Navy Yard for refit; this has worked well and is mentioned with approval. The men are all examined on arrival, those requiring treatment are listed, and the list is sent to the captain, who daily releases for treatment as many men as he can spare from duty. A new list is sent next day, and so on, till all are put right.

A STANDARD FOR MATERNAL MORBIDITY.

LITTLE progress can be hoped for in dealing with what is still commonly called puerperal fever unless the condition is accurately defined. In 1905 the British Medical Association laid down a definition of puerperal morbidity and recommended that it should be adopted as a standard by the medical profession. Although this standard has been largely accepted its general adoption has not been universal. This lack of uniformity is well brought out in comparing the clinical reports of various maternity hospitals and charities. There is the more stringent Queen Charlotte Hospital standard which in some quarters is preferred to that advocated by the Association. Several hospitals have invented entirely new definitions of their own, whilst others have failed to interpret the B.M.A. prototype correctly. We have before us the medical report for 1924 of the British Hospital for Mothers and Babies at Woolwich, the authors of which show two sets of figures " in the absence of any generally accepted standard of morbidity-rate." These are based on the number of deaths which have shown a temperature of (1) over 100·4° F. for 24 hours or more, and (2) over 100° for less than 24 hours. It is a matter of serious concern when an institution as admirable and reliable as the British Hospital at Woolwich denies the existence of a standard of puerperal morbidity; it means that it is impossible to compile any statistics on the subject whatever. Obviously, if we are to avoid absolute chaos, the B.M.A. enactment should be adopted in toto or a new formula should be drawn up more in accordance with the views of obstetrical authorities both in this country and abroad. If the latter course were adopted the various international statistical returns on morbidity could be compared and some idea obtained of the incidence of puerperal infection and the relative value of the many forms of treatment carried out. Could not the medical statisticians associated with the League of Nations draw up a memorandum on the subject and arrange a standard in conformity with the opinion of the leading obstetricians of their respective countries?

THE ANÆSTHETIC PROPERTIES OF PROPYLENE AND ACETYLENE.

SINCE Luckhardt and Carter published in 1923 their discovery of the value of ethylene as an anæsthetic, several experimenters have investigated its homologues. The physical properties of propylene suggested that it would prove a more powerful and safer drug than ethylene. Brown, Meyer and Hopff, and Riggs have experimented with it, and we published recently the report of Dr. F. E. Shipway[1] on this and other new gaseous anæsthetics. The August number of *Anæsthesia and Analgesia*, the publication of the International Anæsthesia Research Society, contains the record of experiments by Prof. J. T. Halsey, Mr. C. Reynolds, and Mr. W. A. Prout at New Orleans. They have found an initial difficulty in obtaining pure propylene, but when this has been overcome rapid and comfortable narcosis can be produced in animals and man by a concentration less than one-half of that required with ethylene.

---

[1] THE LANCET, June 6th, p. 1192.

[1] THE LANCET, 1925, i., 1126.

Death does not result till a concentration 150–160 per cent. of the anæsthetic dose is reached and is usually due to simultaneous failure of the heart and respiration. In animals it was not possible to obtain complete muscular relaxation, but an analgesia sufficient for clinical purposes resulted from concentrations of 40 to 50 per cent.; at which strength there seemed to be no harmful effects and no toxic sequelæ. The authors conclude that propylene may prove of value in anæsthesia, but this can only be determined by cautious clinical trials made by experienced and competent anæsthetists with careful attention to exactness in dosage. The same publication contains a note by Mr. A. Goldman, D.D.S., and Mr. J. D. Goldman, D.D.S., of New York, on acetylene-oxygen anæsthesia. This combination has been extensively tried in Germany. The American investigators have experimented with white mice and conclude that anæsthesia can be maintained with percentages of oxygen much higher than that in air and that the symptoms of danger (gasping) are readily recognisable and appear early enough before respiration ceases for the animal to be easily brought back into safety. The safety margin is much more favourable with commercial acetylene and oxygen than with either ethylene and oxygen or nitrous oxide and oxygen. Dental operations conducted under this anæsthesia were very successful, the subject retaining good colour and returning to consciousness with a hearty appetite ten seconds after the apparatus was removed. It is important to get the acetylene pure; German investigators claim to have freed it from all trace of phosphine and sulphur, but the American workers did not succeed in getting less than 0·0008 per cent. of phosphine and 0·002 of sulphur.

INTESTINAL NEURO-DYSPEPSIA.

UNDER this title Prof. Arturo Campani, of the University of Modena, publishes a description[1] of a syndrome which, though clearly defined, is slight in its effects on the bodily organism, and perhaps on this account liable to be confused with myelasthenia, disturbances of metabolism, or chronic enterocolitis. According to Prof. Campani the malady consists of a stable and characteristic group of fundamental symptoms which are deserving of special study and nomenclature. These manifestations are: (1) Insomnia of a peculiar kind, the patient sleeping soundly till 2 or 3 A.M., then waking with a sense of heat, sweating, and borborygmus. Sleep is resumed with difficulty. (2) Disturbance of intestinal digestion characterised by changes in the rhythm of defæcation, sometimes spasmodic constipation, but more often slight tendency to diarrhœa or to repeated and copious evacuations. (3) Retardation of morning digestion, the patient having no inclination for food after the mid-day meal. (4) An eruption on the dorsal surface of the fingers sometimes so slight as to escape notice unless carefully looked for, characterised by guttate desquamation of the epidermis over the second and third phalanges, with irritable redness of the underlying dermis, more or less evident erythema, never severe, dry, with slight tendency to fissures. Not infrequently the skin of the phalanges is less pigmented and becomes smoother than the rest of the hand. (5) Tingling on the arms and head, retinal hypersensitiveness, muscæ volitantes. (6) Increased plantar and skin reflexes. (7) Tolerance towards adrenalin, intolerance towards belladonna even in small doses. This group of symptoms which form the syndrome is often accompanied by accessory manifestations such as polyuria, hand tremors, and irritability of temper; true psychasthenia, however, is never found. The general health suffers but little; there is not rarely a history of phosphaturia in youth which disappears with the progress of years and develops into a tendency to urinary hyperacidity and calciuria. This syndrome rarely makes its appearance before the age of 40 and is almost confined to the male sex. Its cause may lie in some functional disequilibrium of the endocrine glands causing sympathetic and vagal hypotonus; it usually ceases when true old age is reached. Further elucidation is required to settle what glands or group of glands are most implicated; the disturbances of calcium metabolism and the cutaneous pigmentation seem to suggest a slight suprarenal insufficiency, and Prof. Campani thinks that the cutaneous nervous and intestinal signs have some remote resemblance to pellagrous conditions. Treatment is best directed to elimination from the diet of sugar, cream, chocolate, and sweet farinaceous foods, and to reduce the evening meal to a minimum. Bromide of sodium may be given as an intestinal antispasmodic, and some good effects have resulted from the administration of preparations of lime together with adrenalin.

---

THE ICONOGRAPHY OF VESALIUS.[1]

IN 1912 Prof. Dr. Paul Heger, now president of the University of Brussels, originated a scheme to produce a Liber Memorialis in honour of Andreas Vesalius, to commemorate the fourth centenary in 1914 of the birth of the father of modern anatomy. A subsidy was promised by the Belgian Government and a select band of scholars was chosen to collaborate. Of this project, including biographical, historical, and scientific and iconographic sections, only the last section, which was placed in the competent hands of Mr. M. H. Spielmann, F.S.A., has come to fruition. With the active assistance of Prof. Heger, Mr. Spielmann was able to complete his section, which was set up in type before the other essays were completed. Then came the war, and the whole matter was suspended. After the war it was found impossible to proceed with the scheme, for everyone was more occupied with the future than with the past, and of the band of scholars who had been entrusted with the other sections not less than four had fallen victims to the war, either directly or indirectly. But it was decided to publish the iconography, which was first written in French, the English version being published under the auspices of the Wellcome Historical Medical Museum, forming No. 3 of the series of Research Studies in Medical History. The work is in every way worthy of the distinguished anatomist; we doubt whether so complete an iconography of any one individual has ever before been compiled. Mr. Spielmann has omitted nothing which can throw light on his subject. He deals with portraits in oils, pictures, engravings, illustrations, sculpture, and medals; there are numberless illustrations most admirably reproduced and an iconographic bibliography which is a model of what such things should be, while Mr. Spielmann's critical and literary notes are of extreme interest. The portrait of Vesalius which is the source and ground of all others of him, either directly or indirectly, is the well-known woodcut, dated 1542, which appears in the first edition of Vesalius's great work, De Humani Corporis Fabrica Libri Septem, published at Bâle in June, 1543. The drawing was done by Calcar, but the name of the wood-cutter to whom he entrusted the drawing is unknown, although he was evidently a master of his craft. There are 20 known portraits in oils of Vesalius, or at least claiming to represent him, but of these Mr. Spielmann considers that only nine can be reasonably regarded as true representations. One of them is no longer in existence, although it was so when Mr. Spielmann wrote of it, the famous picture which used to be in the University of Louvain. Besides these oil paintings there exist numerous engravings both of Vesalius alone and showing him demonstrating before an audience, the chief of these latter being the title-page of the Fabrica of 1543. Sculptures and medals are dealt with in the latter portion of the iconography. Of no man of science, we may say, are there so many graphic illustrations as of Vesalius, and when we consider that among the artists are such men as

[1] The Iconography of Andreas Vesalius, 1514–1564; with Notes, Critical, Literary, and Bibliographical. By M. H. Spielmann, F.S.A. London: John Bale, Sons, and Danielsson, Ltd. 1925. Pp. 243. 30s.

Titian, Tintoretto, and Moroni, it is evident that his fame is not posthumous alone. Artists and medical men, together with historians, owe a debt of gratitude to all the begetters of this book.

PATHOLOGICAL INVESTIGATION IN SCOTTISH MENTAL HOSPITALS.

IN Scotland the effort to centralise and develop the study of mental pathology is continuing. The Board of the Scottish Asylums Pathological Scheme report that Dr. F. E. Reynolds has been appointed superintendent of the laboratory with recognition as lecturer in neuropathology to Edinburgh University—a most valuable combination of posts. Dr. Reynolds visits the contributing asylums periodically to advise and encourage the work carried on by individual medical officers, and is himself conducting researches into the paths of infection of the leptomeninges. The laboratory undertakes such routine work as may be desired by the 21 hospitals supporting the scheme, and supplies them with printed forms for description of specimens and circulars explaining the best methods of taking, despatching, and preserving material. A similar scheme is in force in the West of Scotland. It is reckoned that a contribution at the rate of six-tenths of a penny per patient from each of the seven bodies concerned in the scheme would make the financial basis sound. Dr. W. Whitelaw, director of the research institute in Glasgow, reports a steady increase in the routine work done, from 450 specimens in 1921 to 2006 in 1924. Owing to epidemics of typhoid fever at Hawkhead and Greenock Asylums, a large proportion of these specimens were examination of excreta for *B. typhosus* or of blood for Widal reaction. The epidemic at Hawkhead seems to have been present since 1916, but has undergone exacerbation since 1921. Twelve carriers in all have been isolated, and Dr. Whitelaw is of opinion that typhoid will come to occupy the position that dysentery once held if drastic steps are not taken to deal with it. He urges the importance of early recognition and early isolation. Research has been undertaken on blood-sugar in anxiety states, on the calcium content of the blood in epilepsy, and on the cerebro-spinal fluid in general paralysis which is being treated by protein shock; but it is too early yet to formulate conclusions. A number of medical officers have been examining the relation of chronic infection, especially intestinal toxæmia, to certain mental disorders. Treatment by intestinal disinfectants has not yielded any useful results. Dr. J. Neilson, a M'Cunn scholar, is working on the histology of encephalitis lethargica. Certain post-mortem material is being investigated with special regard to the associative mechanism, and Dr. Whitelaw appeals for material from dementia præcox cases. It is clear that while valuable work is being done by these two Scottish schemes, there is still ample scope for extension and improvement.

THE LATE DR. J. DE ZOUCHE MARSHALL.—John James de Zouche Marshall, L.R.C.S. Irel., Lieut.-Colonel, R.A.M.C. (T.), died at his residence in Hove on August 24th at the age of 78. Born in Limerick, he was educated in Dublin, studying medicine at the Royal College of Surgeons in Ireland, where he qualified L.R.C.S. Irel. in 1869, L.A.H. in 1870, and L.M. (Coombe Lying-in Hospital) in 1871. His professional life was spent in England, at Surbiton, Esher, and Hastings, until his retirement some eight years ago, when he took up residence at Hove. While in practice he actively identified himself with the Volunteers, and then with the Territorials in the Royal Army Medical Corps, to which he devoted much of his time and energy. He rose to the rank of Lieut.-Colonel and received the Volunteer Decoration. He commanded the 3rd Home Counties Field Ambulance, was lecturer and examiner to the St. John Ambulance Association, and at one time served in that capacity to the Metropolitan Police. He contributed a number of articles on ambulance work and allied subjects to medical literature. Although in later years declining health prevented him from taking an active part in the affairs of the St. John Ambulance Association, he followed the work of the movement with a never-failing interest.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXVIII.—THE TREATMENT OF PAPILLOMA OF THE BLADDER.

OF the various methods of treatment of papillomata of the bladder, only two will be considered here; in one, the tumour is burnt or coagulated by the passage of an electric current at high voltage, contact being effected by an electrode introduced through a catheterising cystoscope, the method being known as fulguration; in the other, the tumour is removed by operation through a suprapubic incision. The old treatment of washing out the bladder with solutions of various drugs is not curative, and the removal of growths with the operating cystoscope is not advised for reasons which will be clear later.

Two Lines of Treatment.

Each form of treatment has its advantages and disadvantages, and what is suitable for one tumour may be unsuitable for another. Each case must be judged on its merits, and, while no hard and fast line can be drawn, the following points should be taken into consideration when deciding which is the better method for any given patient.

Fulguration possesses these advantages. It can be done without a general anæsthetic, and the patient need only be confined to bed for a day or so, and in many cases not at all; it is therefore valuable for patients for whom a general anæsthetic is contra-indicated or who prefer a cure without a "cutting" operation. It is suitable only for growths which are undoubtedly simple, relatively small, and not numerous; mere multiplicity, however, is no contra-indication, provided the total bulk of the tumours is not too large. It is of the greatest value in dealing with the small recurrences or implants which so frequently occur after the cure of an original papilloma. Experience has shown that there is a somewhat less risk of the occurrence of secondary seedlets on the vesical wall after fulguration than after suprapubic removal.

The disadvantages of fulguration are as follows. As the process of coagulation is slow, the procedure required for the complete destruction of a tumour, unless of small size, is often a lengthy one, frequently several sittings being required, especially when no general anæsthetic is employed. Fulguration is unsuitable for tumours that are sessile, as it is difficult to be sure of their non-malignancy, owing to the impossibility of determining for certain with the cystoscope the absence of infiltration of the vesical wall. It is unsuitable for tumours that are large or very numerous, owing to the number of sittings required and sometimes to the field of operation being obscured by the imbedding of the end of the cystoscope in portions of the growth. Lastly, it is unsuitable for cases in which hæmorrhage occurs on the least provocation and cannot be controlled; hæmorrhage of this type is most likely to take place when the end of the cystoscope butts into and traumatises the growth, which is often near the internal meatus or of large size. Fulguration is difficult to employ when tumours are situated in certain inaccessible positions, such as close to the internal meatus, on the antero-superior surface, and at the back of the retroprostatic pouch.

Removal by suprapubic cystotomy has the advantage of enabling the tumour or tumours to be eradicated at one sitting, and is indicated when the question of non-malignancy is in doubt, or when the tumour is sessile or of large size. It is the only form of treatment for the radical cure of definitely malignant growths, as by its means those tissues which are infiltrated, including portions of the vesical wall of varying extent, can be removed with the tumour. Furthermore, the suprapubic exploration of the bladder affords the only means of determining accurately the presence of infiltration in the earlier stages and the extent of it in the later.

Removal by suprapubic cystotomy has the disadvantage of subjecting the patient to a major operation with its attendant risks and complications and to a period of post-operative convalescence. Generally it is possible to suture the suprapubic vesical wound completely and, in the majority of cases, to obtain primary union without a urinary fistula; in favourable cases, therefore, the patient is confined to bed for a fortnight, while in those in which a fistula occurs, the wound will take from three to six weeks to heal. The occurrence of secondary seedlets is more common after this method of treatment than after fulguration, but is in part probably due to the more serious tumours being dealt with by this method. Recurrences, however, do take place not uncommonly in the suprapubic vesical scar and rarely in the scar of the abdominal wall.

In deciding which is the method of choice in a given case, in addition to the above considerations, due regard must be given to the temperament of the patient, his ability to attend for treatment, and his own views on the matter. Some surgeons are more strongly in favour of fulguration and others of removal by suprapubic cystotomy.

Of all the points to be taken into consideration, the determination of the innocence or malignancy of the tumour is the most important, and is often difficult. The signs suggesting malignancy are—the presence of sloughs or phosphatic deposits on the surface of the tumour; a ragged and torn appearance of its villous processes; the absence of a narrow pedicle; the presence of infiltration, which is responsible for a diminution of the normal vesical capacity and for the symptom of frequency; and the presence of a tumour on bimanual examination of the pelvis.

Whichever method is adopted, however, some important pathological properties of vesical papillomata must be borne in mind. First, the ease with which cells of, or portions of, the tumour will implant themselves, and grow, on the apparently intact mucous membrane of the bladder and in other tissues of the host; secondly, the frequency with which multiple tumours occur; thirdly, the frequency with which other and similar growths appear in the bladder months or years after the complete removal of the first; fourthly, the vagueness of the line of demarcation between a simple and malignant tumour, and the fact that a simple papilloma sooner or later usually becomes malignant if untreated. It is clear, therefore, in treating papillomata of the bladder that as far as possible living cells or portions of the tumour should neither be allowed to come in contact with the vesical wall or other tissues of the patient nor be left behind lying free in the bladder, and that, after the cure of one papilloma, the bladder, even in the absence of symptoms, should be examined with the cystoscope every two, or at most three, months at first, and later every six months, over a period of many years.

Technique of Fulguration.

The employment or otherwise of a general anæsthetic varies with the practice of different surgeons. Its use may enable a growth which would otherwise require several applications to be destroyed at one sitting; moreover, the surgeon's attention is not distracted by the thought of giving the patient pain or discomfort; on the other hand, its use adds a definite risk, small though it is. Without a general anæsthetic, the duration of the treatment is limited by the fatigue of the patient induced by the presence of the cystoscope in the urethra, by the discomfort of the distended bladder, and by the pain caused by accidentally touching the sensitive trigone; moreover, the patient, and to some extent the surgeon, are under mental tension throughout. Generally speaking, the smaller the growth, the older the patient (the bladder and urethra being less sensitive in the aged), and the more stolid he is, the less the desirability of a general anæsthetic.

One terminal of the apparatus is connected to a malleable metal plate, which is firmly bandaged to the thigh, suprapubic region of the abdomen, or back. The bladder is gently distended with fluid, the catheterising cystoscope introduced, and the electrode, connected with the other terminal of the apparatus, inserted into the cystoscope. To prevent living cells, or living portions, of the tumour from becoming detached during the subsequent procedure, the surface of the growth should as far as possible be dealt with first. The electrode is gently pushed on to the tumour so that its point lies among the villous processes and in contact with them, and the current turned on. In a few seconds the part of the growth immediately around the electrode turns white, then black, and a little later bubbles begin to appear accompanied by a sound of fizzing and the appearance of an arc. As little arcing as possible should be allowed to occur, and on its appearance the electrode is withdrawn a little, the current switched off, and the procedure repeated at a fresh place. It is important during the withdrawal of the electrode to avoid as far as possible the risk of pulling off pieces of living growth, as, apart from the theoretical objection of liberating living tumour cells, hæmorrhage is liable to be produced; this risk is lessened by keeping the current switched on during the withdrawal; portions of coagulated tissue will, however, often become firmly glued to the electrode and will come away with it. In the case of the smaller tumours the whole growth and its pedicle can in a short time be destroyed in this manner; it is, however, essential to treat a small area of apparently normal mucous membrane immediately surrounding the place of origin of the tumour in the same way; in the case of the larger pedunculated tumours, time can often be saved by cutting through the pedicle, a procedure, however, only to be adopted after the surface of the growth has first been coagulated.

During fulguration the electrode has to be removed frequently and its point scraped free from the pieces of coagulated tissue which become firmly adherent to it and prevent the conduction of the current; from time to time, too, the fluid in the bladder must be changed, partly because of its rise of temperature, which is considerable if much sparking has been allowed to occur, and partly because of its diminution in translucency caused by the presence of blood and particles of coagulated tissue. Should bleeding occur, it can usually be stopped by leaving in the bladder for a few minutes some fluid containing one or two ounces of 1 in 1000 adrenalin solution.

Sometimes, in treating a papilloma growing in the middle line of the trigone, difficulty is caused by the repeated accumulation of bubbles on the lens of the cystoscope obscuring the view; the difficulty can be avoided by turning the patient on his side.

Papillomata growing on the anterior vesical wall, usually recurrences in the scar of a previous suprapubic cystotomy, may be brought into closer relationship with the electrode by an assistant placing his hand on the suprapubic region and pressing backwards the anterior abdominal wall and by only partly filling the bladder with fluid.

If fulguration is carried out under a local anæsthetic, half an hour is about as much as the patient will tolerate, while if under a general anæsthetic, it can be continued for say an hour and a half, but has then to be stopped, sometimes owing to fatigue of the surgeon, sometimes to hæmorrhage obscuring the field of operation, and sometimes, after the whole surface of the tumour has been coagulated, to the necessity of awaiting the separation of the sloughs before the amount of living tumour remaining can be determined.

At the end of the sitting the free sloughs are evacuated with a Bigelow's evacuator, and some surgeons wash out the bladder with a 1 in 10,000 silver nitrate solution with the object of killing any loose living tumour cells.

Post-operative treatment calls for no special comment. Some urethral discomfort from the presence of the cystoscope in the urethra is usual and a little hæmaturia may occur, but is not severe. In cases in which the tumour or tumours cannot be completely destroyed at one sitting, the next treatment should be undertaken three weeks or a month later. If at the second sitting it is found that no marked diminution in the size of the growth has occurred, its non-malignancy is in grave doubt.

Technique of Suprapubic Removal.

The patient is given a general anæsthetic and the bladder gently distended with fluid. A long paramedian incision is made, extending from the symphysis pubis to the umbilicus or above, the rectus sheath opened, and the peritoneum stripped off the anterior wall of the bladder as far upwards as practicable. To avoid the possible contamination of the wound with living tumour cells which might perhaps be suspended in the fluid, the bladder may now be emptied by the catheter left in situ for the purpose. The patient is put in the Trendelenburg position and the bladder opened by a long vertical incision in its anterior wall. The wound, shielded with rubber pads, is held widely retracted in a good light. Thompson Walker's self-retaining illuminating retractor is useful. Any fluid remaining in the bladder is removed either by a suction tube or by pieces of gauze, care being taken not to touch the papilloma. The amount of infiltration of the vesical wall, if any, must be determined. It is wise as a first step to destroy the whole surface of the tumour with the benzoline or electric cautery or the diathermy apparatus. In the case of the smaller growths, their complete destruction and that of their pedicles and adjacent vesical mucous membrane can be accomplished in this way. In the larger but pedunculated growths, the root of the pedicle is seized with suitable forceps, after the preliminary cauterisation of the surface of the growth, and the tumour with a portion of the normal vesical mucous membrane cut or burnt away; the seizing of the tumour itself with forceps should never be done, as it will almost certainly cause hæmorrhage and the tearing off of portions of the growth. In dealing with the larger but sessile tumours and with those in which infiltration has occurred, a piece of the whole thickness of the vesical wall should be removed with the tumour by means of the knife or cautery, the line of section being kept well clear of the infiltrated tissue. The resulting wound, if made by the knife, is sutured with catgut after ligating the bleeding points, but if made by the cautery is best left to granulate after separation of the sloughs; should the whole thickness of that part of the vesical wall which is covered by peritoneum need to be removed, the knife should be used and the wound carefully sutured. If the tumour is growing on or near a ureteric orifice, no hesitation need be felt in removing that orifice or even a portion of the ureter itself if necessary. In many cases the vesical mucous membrane upon which the papilloma has been resting is dark red, granular, and velvety; the whole of the area thus affected should be cauterised. If thought desirable, the bladder may be washed out with a solution of silver nitrate. Some surgeons prefer to close the suprapubic vesical wound completely, drainage being established by a catheter tied into the urethra for a few days, while others prefer to provide suprapubic drainage; generally, suprapubic drainage is unnecessary unless hæmostasis is incomplete; but sometimes secondary hæmorrhage occurs during convalescence when the sloughs separate, and occasionally is so free as to necessitate reopening the suprapubic wound.

During convalescence the urine should be kept acid and the patient given hexamine, and it is as well to commence the use of this drug a day or so before operation. Whether the patient is submitted to bladder washes or not depends on the practice of different surgeons. In the majority of cases in which suprapubic drainage has not been adopted, the wound heals per primam, and the patient is out of bed at the end of a fortnight; in those in which a suprapubic fistula occurs, the wound closes in from three to six weeks.

At the subsequent cystoscopic examinations very careful inspection should always be made of the suprapubic vesical scar, as recurrences in that situation are not uncommon.

For the undoubtedly malignant tumours an operation planned on the lines indicated above should be performed, a more or less extensive area of the whole thickness of the vesical wall being removed, the procedure amounting to a partial cystectomy. Inoperable cases are of two types. In one the bladder is filled with a mass of papillomatous growth; the only radical treatment is total cystectomy, an operation having so high a mortality that it is rarely performed; sometimes the whole mass of the growth is curetted out and the bladder cauterised, a procedure which, besides causing severe hæmorrhage difficult to control, is almost certain to be followed by recurrence. In the other type the growth invades the extravesical tissues, producing a large, firm, fixed pelvic mass. For both types, in addition to the treatment of symptoms, radium may be employed with advantage; sometimes the patient's existence is so miserable that it is advisable to put the bladder out of court by a bilateral ureterostomy, the ureters being either brought to the surface or inserted into some part of the intestinal tract.

B. C. MAYBURY, F.R.C.S. Eng.,
Surgeon to Out-patients, St. Thomas's Hospital.

Obituary.

JOHN DARLEY WYNNE, M.B., B.CH. DUB., D.P.H.

Dr. J. Darley Wynne, who died on August 4th in Guernsey, was the second son of the late Right Rev. F. R. Wynne, D.D., Bishop of Killaloe. He was educated at St. Columba's College and graduated in arts and medicine at Trinity College, Dublin, gaining the Hudson prize and silver medal of the Adelaide Hospital. He began his medical career in Sheffield, where he was for a time house surgeon to the Jessop Hospital for Women. He was afterwards medical officer to the Nottingham Borough Fever Hospital, and having also gained experience of general practice in that city he returned to Ireland and was for many years one of the leading practitioners in Clonmel, Co. Tipperary. It was during this period that he turned his attention to public health matters, and took with honours the diploma of the Irish Royal Colleges. He was one of the pioneers of the special study of tuberculosis in Ireland and published several papers on the subject, one of which on the Connexion between Cattle Fairs and Tuberculosis in Ireland was an important piece of original observation. Another paper on Dr. Johnson and the Medical Profession was the outcome of a discerning knowledge of English literature. After a severe illness Dr. Wynne left Ireland and took a country practice in Norfolk, but continued ill-health compelled him to seek less strenuous work in Guernsey where he died. In spite of physical disability he remained a hard worker and a keen sportsman almost up to the day of his death; in fact, the final failure of his heart seems to have been determined by a bathe in the sea three days before he died. Yachting, boat-sailing, and swimming were his recreations, and he never lost his love of them. To those who knew him best he was a man who had not lost the charm of youth in spite of ill-health, and he is still remembered with affection by his old colleagues in Sheffield and elsewhere. He leaves a widow and three children.

end of the phase; but as the volume of blood flowing through the lungs is itself diminishing during the same period, so the blood leaving the left heart will contain a more or less constant percentage of CO_2.

A gradually decreasing volume of CO_2 is washed out of a gradually decreasing volume of blood, and the ratio between the two seems to be maintained by the degree of closure of the glottis. The mechanism is the reverse of that occurring during inspiration.

Relation of Respiratory Movements at the Glottis to other Factors.

What has been described appears to be the chief function of the respiratory movements at the glottis of man, although it is not a primitive function.

(*a*) *Oxygen-content of Alveoli and Blood.*—I had supposed that the mechanism of correlation between air entry and blood-flow was directed towards regulation of oxygen exchange; by Prof. McDowall's aid I was enabled to see the error of this view, and it was at his suggestion that I reconstructed the theory to apply to CO_2 exchange. In some aquatic mammals regulation of oxygen-content of the alveoli and blood seems to be a function carried out by the glottis; in man this does not appear to be the case. The percentage of oxygen in the alveolar air even at the end of expiration is almost always high enough to saturate the blood, and from this we see that it is obviously unnecessary for the glottis to take part in regulation of oxygen-content of the lungs.

(*b*) *Relation to Aortic Blood Pressure.*—The respiratory movements have a marked influence on the blood pressure, because of the factors already mentioned—namely, the increased flow of blood through the lungs during the major part of inspiration and the diminished flow during expiration. The normal respiratory waves depend to a considerable extent on the descent of the diaphragm and not merely on the alterations in pressure within the thorax; but the latter factor is the more important of the two. In comparison to the usual high level of aortic blood pressure, however, the respiratory variations would not appear capable of exerting any marked influence; they would seem to be merely incidental to the mechanism designed for regulating the reaction of the blood, and not to be directed purposely to maintenance of the blood pressure in the systemic circulation. It is the power of the left ventricle which maintains the very high pressure in the aorta.

(*c*) *Pump Action on Circulation.*—Sir Arthur Keith has impressed on me the great importance of another closely related factor—namely, the pump action of the respiratory movements in drawing blood through the lungs, and of thus assisting the circulation. The inspiratory pump action has already been described as regards its relation to CO_2 exchange, in which respect it appears to be extremely important. As to the assistance given to the heart in causing circulation of blood round the body, the effect is proportional to the difference between the increase of volume of blood drawn into the right heart and great veins and so to the lungs on inspiration, and the decrease of volume consequent on slight compression of the right heart, and especially of the great veins during expiration.

In relation to the work of the heart the glottic movements would seem to exert a definite and important function in conjunction with the other factors such as the mechanical compression of veins and the action of CO_2 on the venous reservoirs, which promote the return of blood to the heart and increase the rate and output of the latter. It was stated above that the movements of the glottis have little effect on the height of aortic blood pressure, because the differences noted between inspiration and expiration are slight and almost negligible when compared to the high level present in the great systemic arteries. But as regards the right side of the heart the effect is marked. The pressure in the pulmonary artery is very low as compared with that in the aorta, and any assistance given by the mechanism described during inspiration is of great benefit in maintaining efficient circulation through the lungs. On the other hand, any obstruction offered during expiration exerts a marked influence. These variations, in allowing more or less blood to reach the left ventricle, will indirectly affect the level of aortic blood pressure, but it should be clear that there is a difference as regards the action of the glottis in the two respects—namely, that great assistance is given to the work of the right side of heart, while little is afforded to that of the left.

(*d*) *Effect on Hering-Breuer Reflex.*—When the lung is distended at the end of inspiration a stimulus passes up the vagus which instigates the commencement of expiration. At the end of expiration another stimulus causes inspiration to begin. The obstruction offered by the glottis to passage of air causes prolongation of the time taken to fill or empty the lung and thereby causes suitable delay in the timing of the signals for emptying or filling of the lungs—namely, the Hering-Breuer reflex. The importance of this mechanism has already been emphasised. Lumsden considers that passage of air either into or out of the air passages gives the signal referred to as the Hering-Breuer reflex.[4] Such a view does not alter the significance of the part played by the glottis in the mechanism.

(*e*) *Regulation of Filling of Alveoli.*—From observation of certain facts related to comparative anatomy it appears to me that obstruction offered by the glottis during expiration may have an important effect in assisting to distribute air in the air sac systems, and in helping to fill those alveoli distally situated. The mechanism would be considerably aided by contraction of the bronchiolar musculature at the beginning of expiration, because the bronchioles contract before elasticity of the pulmonary tissue or contraction of the expiratory muscles have had time to expel air from the lungs to any marked extent.

At the same time diffusion of gases from and to tidal air is reinforced by the process of mechanical mixing, probably to a most important degree. It is suggested that air is drawn from the alveoli, air sacs, and alveolar ducts into the bronchioles at the beginning of inspiration; and that at the beginning of expiration some air is driven from the contracting bronchioles into the terminal ramifications of the lungs. The subject is too big to be discussed further at this point; it will be dealt with in a separate paper.

ALTERATIONS UNDER CERTAIN PATHOLOGICAL CONDITIONS.

Reason for Priority of Abductor Paralysis.

If the recurrent laryngeal nerve be slightly injured, there is loss of power in some of the muscles supplied by it; power disappears from the abductors sooner than from the adductors. This to me is natural, because adduction is an older function than is abduction, and therefore the power of the former survives that of the latter. *Lepidosiren*, a lung fish, has a sphincteric band of muscle at its larynx, which has the power of closing the aperture in the manner of a purse string and of protecting the delicate lungs from the entrance of irritants such as food or water. It has no abductor muscles, according to my observations, and needs none, because passive relaxation of the sphincter is all that is required to allow passage of air into and out of the lungs. In other animals such as *Ceratodus*, another lung fish, dilator fibres are present, so that opening of the glottis can be attained more rapidly and more widely; the sphincteric band is, however, of more primitive origin than are the dilator fibres. In mammals the sphincteric band is split up into various components—namely, the thyro-arytenoid, lateral crico-arytenoid, and inter-arytenoid muscles—while the dilator fibres are represented by the posterior crico-arytenoid. In an animal such as a mongoose the sphincteric group is used mainly for protective closure of the larynx, but not at all for phonation; while the dilator muscles are for opening the glottis on inspiration, just as in *Ceratodus*.

In man and many animals certain fibres of the sphincteric group are used for phonation; this is, however, a comparatively new and subsidiary function, as pointed out in my Arris and Gale lecture, and does not alter the fact that the primary object of the group is for protective closure. Therefore in man, as in lung fish, the function of adduction is of older standing than is that of abduction, and in consequence it survives longest. In cases of abductor paralysis in man the paralysed cord lies nearer to the mid-line than the cadaveric position, because of tonic contraction of the adductor group. In health the position is determined by active contraction of the abductors,[4] balanced by opposition of the adductors, associated with resistance of elastic fibres in the crico-arytenoid joint; the latter tend to bring the cartilages and cords into the cadaveric position.[5]

Effect of Laryngeal Obstruction.

Obstruction to passage of air through the larynx may be due either to paralysis of the muscles which open the glottis or to spasm of those which close it, or to local conditions which cause mechanical blockage. If there is merely inability to abduct the vocal cords, then difficulty will be experienced on inspiration only, because of the valvular nature of the glottic margins, which are flat above and conical below. Spasm of the sphincteric muscles will produce effects similar to those of paralytic obstruction; but in the former case the condition is overcome as soon as asphyxia commences, while in the latter it is permanent. As there is nothing particular to describe in the present connexion, spasmodic conditions will not be considered separately. If the pathological process has produced marked narrowing of the laryngeal passage, then obstruction will be offered during both inspiration and expiration. Combinations of the two types of paralytic and mechanical obstruction are met with; they will give rise to mixed effects.

(1) *Inspiratory Obstruction.*—One important result of inspiratory obstruction, usually due to abductor paralysis, will be upset of the normal mechanism of washing out of CO_2 from the blood. At the beginning of inspiration in these cases there is considerable delay in the passage of air through the glottis, and therefore there is not dilution of CO_2 in the alveoli at the usual rate. But the intrapulmonary and intrathoracic pressures during this phase are lowered more than usual, because the increasing capacity of the lungs is not filled by inrushing air as quickly as is normal. The abnormal lowering of pressure in the thoracic cavity causes an unusually large volume of blood to flow through the lungs as an exaggeration of the usual increase; as the percentage of alveolar CO_2 is higher than it should be there is less of the gas washed out of the blood. Consequently the blood leaving the lungs and travelling to the tissues contains a higher percentage of CO_2 than in a normal individual during this period; a certain degree of breathlessness is produced because of this relative retention of CO_2. Towards the end of inspiration entry of tidal air reaches its maximum and there is therefore dilution of alveolar CO_2, so that blood CO_2 falls in consequence.

On expiration there is the usual mechanism of washing out of CO_2 in cases of abductor paralysis, because, although the failure of the muscles which open the glottis does not permit attainment of the desired width of the aperture, yet the abductors and elastic fibres are still capable of closing it to the requisite degree, while simple relaxation of the sphincteric muscles will allow the funnel-shaped margins to be blown open in a mechanical manner when the force of expiration is great enough to necessitate wider opening at the larynx. Therefore "sympathetic connexion" is not upset during this phase. This is the effect on washing out of CO_2 during the different phases of respiration; it is seen that the normal correlation between inspiratory entry of air and volume of blood passing through the lungs is upset, and that the CO_2 content of the arterial blood is in consequence no longer constant, tending in the mean result to be higher than usual, and thus causing breathlessness. Other effects are due to the diminution in volume of tidal air because of the abnormal obstruction on inspiration. The CO_2 percentage of the arterial blood tends to rise if lung ventilation becomes insufficient. It is raised also because of the abnormally insufficient washing out of CO_2 at the beginning of inspiration; a combination of all these factors leads to increased stimulation of the respiratory centre.

The result will be increased effort on inspiration and a temporary compensation of the laryngeal obstruction, and return of blood CO_2 to the normal level. The increased effort is not able, however, to keep pace with the accumulation of CO_2 in the alveoli; therefore the CO_2 in the blood again rises and the respiratory centre has to accommodate itself to respond to a permanent new level. The level may reach as high as 7·5 per cent., as in a case investigated by Dr. R. D. Lawrence and myself.

As to supply of oxygen to the lungs. In the early stages anoxæmia is not produced because of the normal surplus of oxygen contained in the alveolar reservoir; the colour of the patient is therefore good. But as the total volume of tidal air per minute decreases, there will come a time when the hæmoglobin does not find sufficient of the gas to saturate it. A further factor depends on an observation made by Haldane (p. 157).[3] If the blood-flow through the lungs is abnormally accelerated, as it is in these cases during the early stages of inspiration, there may not be time to pick up what oxygen is available; therefore the condition of anoxæmia is aggravated. The effects of anoxæmia on the respiratory centre are to stimulate it in a jerky manner and to hasten an early failure of the controlling mechanism of respiration, which is due chiefly to the continued excessive stimulation by CO_2.

(2) *Complete Paralysis.*—Cases of complete paralysis of all the muscles controlling the glottis will show the same characters during inspiration as those already described; during expiration, however, the flabby passive opening of the aperture will not offer sufficient resistance to the current of air. The result will be that the blood-flow during expiration is not decreased to the requisite extent and insufficient CO_2 is washed out. Therefore, not only is arterial blood CO_2 excessively high at the beginning of inspiration, falling towards the end of the phase, but it also tends to rise above the normal during expiration. The total result is that the respiratory centre is abnormally stimulated and calls for increased effort on the part of the respiratory muscles. The other factors do not differ materially from those seen in abductor paralysis.

(3) *Narrowing of Laryngeal Aperture.*—There will be the same effects during inspiration as those produced in paralytic affections; during expiration, however, there is a difference. Obstruction during the latter phase leads to further decrease in the volume of tidal air per minute; it tends to prolong the Hering-Breuer reflex stimulus for inspiration, but this tendency is counterbalanced by increasing CO_2 content in the alveoli—with absolute CO_2 retention—and usually by a certain degree of anoxæmia. Therefore the rate of respiration tends to rise, while the force increases. The circulation through the lungs is impeded more than in health, because of the increased pressure brought to bear on the right auricle and great veins and on the pulmonary capillaries. Consequently, sufficient blood for the needs of the body cannot pass through to the left side of the heart during this phase of circulation; the veins become engorged with unoxygenated blood and cyanosis appears at a much earlier stage than in cases of pure inspiratory obstruction.

(4) *Treatment of Laryngeal Obstruction.*—With regard to the treatment of cases of laryngeal obstruction, it must be remembered that prolonged deficiency in lung ventilation and upset in the correlating mechanism between air entry and blood-flow lead to increase in the percentage of alveolar CO_2 before signs of anoxæmia appear. Therefore tracheotomy should be performed early and should not be delayed until

urgent symptoms arise. When the condition has become extreme it is often necessary to perform emergency tracheotomy. By this operation lung ventilation is suddenly and enormously increased. Paradoxical as it may seem, even when obstruction has been relieved, there are some cases in which death has taken place, as Sir StClair Thomson has pointed out to me. Therefore it seems necessary to consider the causes and means of avoiding such calamities. In this respect Haldane writes that if the amount of CO_2 in the blood and tissues is greatly reduced by effective artificial respiration for some time, there is prolonged apnœa, and the animal dies of want of oxygen without attempting to draw a single breath; he states that this occurrence has been described by Yandell Henderson.[9] The experiment may be carried out personally by deep breathing while resting, when apnœa is produced.

Dale and Evans[10] showed that a certain percentage of CO_2 was necessary for efficiency of the vasomotor centre, apart from any question of the action of the respiratory centre; this factor was said to play an important part in the difficulties encountered in the attempt to climb Mount Everest. With regard to the observation of Yandell Henderson mentioned above, Haldane adds: "This important experiment shows that when the CO_2 pressure is reduced below a certain point in the respiratory centre, the latter ceases to respond to even the extremest stimulus of want of oxygen."[8] It is apparently the sudden withdrawal of CO_2 from the alveolar air and blood, and the consequent inactivity of a respiratory centre temporarily set to respond to a less alkaline blood reaction caused by the high percentage of CO_2, that leads to danger in tracheotomy. The problem was elucidated by Prof. McDowall, and in conjunction with him and Dr. R. D. Lawrence I hope to make further investigations of the cause of this occasional unfortunate occurrence, and the means of avoiding danger in such cases. It is sufficient to mention at present that the line of preventive treatment is directed to gradual lowering of the CO_2 percentage of the blood, either by injections into the blood itself or by the addition of CO_2 to the inspired air.

In the absence of complete data, however, the observations outlined are not intended to represent final conclusions.

Effect of Tracheotomy and Total Laryngectomy.

When the regulating mechanism of the glottis is thrown out of action many alterations affect the economy of the individual, and may take the subjective form of depression and an inability for exertion; in some patients the scene is terminated by suicide. Warming the inspired air is not sufficient to combat these ill-effects, and therefore other causes must be sought for. It would be surprising if total abolition of whatever influence is exerted by the respiratory movements of the glottis should be unattended by serious effects, and therefore it will not appear strange if the main factor at work can be traced to removal of the glottic valve from its controlling position. After opening of the trachea the same total volume of air enters and leaves the lungs during each minute if the activities of the body are maintained at the same level as before the operation.

But the lungs are filled more rapidly and emptied more rapidly than before the operation, because the delaying action of the obstructive glottis has been removed from the path of the air-stream. Consequently, the Hering-Breuer reflex is more rapid in *onset* than before, and rate of breathing appears to be faster than in the healthy individual. The actual rate observed on 274 occasions in 12 subjects of tracheotomy was on the average 22·83. In one patient after the operation —because of double abductor paralysis—the average rate was 27·8, while the average pulse-rate was 98·4. If more respirations are taken each minute, then each one must be shallower than is normal; that is to say, the tidal volume of air at each respiration is diminished.

These alterations in the mode of air entry are of great importance in the question of removal of CO_2 from the blood. At the beginning of inspiration in the tracheotomy patients a considerable volume of air enters the lungs suddenly and lowers the percentage of CO_2 in the alveoli; consequently, a large volume of CO_2 is washed out of the blood during this period. But there has not been the usual fall in pressure within the pulmonary and pleuro-pericardial cavities, because air entry is so free that it can keep pace with the expansion of the thoracic walls, and can fill the increasing space as soon as it is created. There is still, of course, a certain diminution in intrathoracic pressure because of the influence exerted by elasticity of the lungs; but the total effect on blood-flow through the lungs is definitely less than when the glottis is in action. Consequently, the sudden dilution of alveolar CO_2 is not associated with any marked increase in the volume of blood flowing through the lungs. As this volume of blood is less than during normal inspiration, and as much CO_2 is washed out of it, therefore the CO_2 content of the arterial blood will be less at the beginning of inspiration than during health.

Towards the end of inspiration the flow of blood through the lungs increases, but the washing out of CO_2 does not increase. As a result the CO_2 content of arterial blood rises, and some blood passes through to the systemic circulation insufficiently depleted of the gas.

At the beginning of expiration the tidal air escapes rapidly from the lungs; but there is not the usual increase in intrapulmonary and intrathoracic pressures, because of the absence of obstruction at the glottis. Therefore the blood-stream continues to be of a greater volume than is normal. And as the alveoli have lost their tidal air early, they are gradually accumulating CO_2 until the percentage of the gas rises above the usual level. When this happens the percentage of CO_2 in the arterial blood must also rise because the one follows the other. As a result the CO_2 content of blood leaving the lungs on its way to the tissues continues to rise during expiration; at the beginning of inspiration it will suddenly drop again, as already pointed out.

To sum up: The CO_2 percentage in the alveoli falls suddenly at the beginning of inspiration, and rises considerably towards the end of expiration, while the volume of blood flowing through the lungs rises but slightly during inspiration and is decreased to a less degree than is normal during expiration. The result is that the CO_2 content of the blood supplied to the tissues is lower than normal at the beginning of inspiration and rises towards the end of inspiration and more so still during expiration. There is relative retention of CO_2, which leads to breathlessness, in the same manner as in pneumonia. The changes described will not affect oxygenation of the blood, because the hæmoglobin will be almost saturated, provided there is a sufficient supply of oxygen in the alveolar reservoir.

The supply in the alveoli will be adequate as long as a volume of tidal air arrives at each inspiration sufficient to replace the oxygen which has been taken up by the blood. After opening of the trachea the mechanism will be efficient for this purpose at ordinary times; it is immaterial whether the alveolar oxygen is replaced in jerks instead of in a steady and prolonged stream as in the normal individual. It is possible that upset of distribution of air through the alveoli is another factor dependent on absence of obstruction at the glottis during expiration. Furthermore, the mechanism of air mixing referred to must be obliterated to a certain degree. If contraction of the bronchioles is able to expel air easily through the trachea, there will be an absence of *blow-back*; replacement of oxygen and removal of CO_2 will then depend on diffusion to a greater degree than is usual. As an incident it will be found that the respiratory waves in the aortic blood pressure are distinctly less marked than in the healthy subject; the mean blood pressure need not, however, show any divergence from that usually seen, because of the many factors capable of compensating for the altered mechanism of respiration.

It will be understood, when these disorganisations of a marvellously delicate mechanism are recognised, why certain individuals cannot tolerate life with an open trachea, and prefer the escape of suicide. But there is no reason why the pulmonary air tract should not be fitted with an automatic valve capable of reproducing the movements of the glottis, and of re-establishing "sympathetic connexion" between respiration and circulation; such a valve is in course of construction.

Results of Nerve Anastomosis.

The working of the respiratory centre has been elucidated by Lumsden,[8] who describes the normal mechanism as due to periodical rhythmical inhibition of inspiratory tonus. When this inspiratory tonus is inhibited expiration takes place chiefly as a passive act; the latter phase can, however, be actively stimulated from a special centre. Afferent impulses travel up the vagus to the respiratory centre and determine the timing of the phases of respiration. The stimulus for these impulses has been referred to distension or emptying of the lungs, but is thought by Lumsden to be due during easy breathing to passage of air into and out of the lungs.[8] The respiratory centre during the inspiratory period sends stimuli to various muscles, and at the same time it causes the glottis to open because of certain impulses carried by the recurrent laryngeal nerves. The degree of opening of the glottis is determined by the relation of contraction of the dilator group of muscles to that of the sphincteric group. Both sets are in contraction, but during inspiration the action of the abductors is much more powerful than is that of the adductors. The glottis opens before inspiratory movement of the diaphragm commences, and closes before expiration begins, according to observations made on cats by McDowall and myself. Therefore contraction of laryngeal and diaphragmatic muscles is not synchronous.

The factors at work in determining the position of the vocal cords have been described by various authors, notably by Semon.[4] If a stimulus be sent along the recurrent laryngeal nerve as a whole, the glottis closes, because the action of the adductors is more powerful than is that of the abductors. Therefore the stimulus during normal inspiration, which causes the glottis to be held open, must be a selective one, and directed more powerfully to the dilator muscles than to the adductors. After anastomosis of the recurrent nerve in certain paralytic conditions, either to the descendens hypoglossi,[11 12] or to the phrenic,[12] movement of the affected cord may recommence. As there is in these cases a selective stimulus directed to the abductors, it is probable that impulses must originate from different parts of the nucleus of the nerve employed for anastomosis, and stimuli must be supplied to this particular part of the nucleus from the respiratory centre. The phrenic nerve, for instance, must send powerful stimuli to the diaphragm during inspiration, and only feeble ones or none at all during expiration, because this muscle is active only during the former phase, and is passively relaxed during the latter. Therefore it may be supposed that if part of the phrenic be anastomosed to the recurrent laryngeal nerve, and if the nerve were to carry stimuli of the same character as before, there would be impulses sent along all the fibres of the recurrent nerve during inspiration, impulses intended to reach the diaphragm.

It must be remembered that there is no primitive connexion between the larynx and diaphragm. The former is present, and shows definite respiratory movements at the glottis, in many animals in which the latter is absent, as, for instance, in amphibians and reptiles. Any general stimulation would cause closure of the glottis, because of the superior power of the adductors as compared with the abductors. It has been shown that the fibres serving the abductors travel together in a bundle distinct from those going to the adductors[13]; the two groups can be separated in the vagus, and must obviously originate from distinct groups of nerve cells. After anastomosis the abductor fibres must be replaced by a bundle of phrenic fibres in a corresponding position; these must originate from a distinct group of cells. Consequently, it is to be supposed, in view of the fact that abduction of the cords occurs during inspiration, that this new group of cells from which the abductor fibres originate receives a selective stimulus from the respiratory centre, or else that the group supplying the adductors is inhibited, thus allowing tonic impulses to bring about opening of the glottis because of the unopposed action of the abductors.

The results obtained by Ballance and Colledge and others appear to be remarkably successful when these aspects of the subject are considered. But even when this extraordinary selective result has been attained success is not perfect unless the glottic aperture is enlarged to the requisite degree in accordance with the immediate needs of respiration. Wide opening on gentle breathing, or slight opening in forced respiration does not fulfil the conditions necessary for the delicate mechanism described. Although the result is admirable for ordinary purposes and allows of successful respiration and phonation, yet the fine adjustment is lost. If the opening is too big the conditions resemble those described in the case of tracheotomy; while if it is too small then a certain degree of laryngeal obstruction is present, with its varied effects. There is, in brief, a loss of that "sympathetic connexion" referred to by John Hunter, whose brilliant example has supplied the incentive for this attempt at elucidation of certain aspects of a somewhat complex problem.

Research directed to the subject of this paper has been carried out, by permission, in the laboratories of: (1) The Zoological Society of London; (2) the Royal College of Surgeons of England; (3) the Physiological Department, King's College, London; (4) the Throat and Nose Department, King's College Hospital; to the authorities in each case gratitude is expressed. Data relating to the effects of tracheotomy were kindly supplied by the medical superintendent of St. Giles's Hospital, Camberwell, the registrar of the Central London Throat and Ear Hospital, and the surgical registrar of King's College Hospital.

THE LATE DR. J. F. S. HAY.—Joseph Frank Strong Hay, M.B., C.M. Aberd., Inspector-General of the New Zealand Mental Hospitals, died on Sept. 5th at sea, while returning to New Zealand after a visit to England. Dr. Hay graduated in medicine at Aberdeen University in 1890, and shortly after became assistant medical officer at James Murray's Royal Asylum, Perth, Scotland. He was then appointed to the post of physician-superintendent at the Ashburn Hall Asylum, Dunedin, New Zealand, and subsequently became Inspector-General of Mental Hospitals and Prisons in that country.

ON IMMUNITY TO THE TOXIN OF STREPTOCOCCUS SCARLATINÆ.

A Report to the Medical Research Council.

BY HERBERT HENRY, M.D. LOND.,

AND

F. C. LEWIS, M.R.C.S. ENG.

(From the City of Birmingham Bacteriological Laboratories.)

PART I.

A MEASUREMENT OF IMMUNITY AS DETERMINED IN CHILDREN AND IN ADULTS BY THE INTRADERMAL TITRATION OF MULTIPLE DOSES OF TOXIN.

AT present there is not available an in-vitro test or an animal test by which the toxin of *Streptococcus scarlatinæ* can be measured, so that for purposes of titration recourse must be had to the skin test on human beings. It may be assumed that a strong Dick toxin will give a positive reaction with the majority of individuals, while the same toxin can be diluted so far that it yields no positive reactors at all. It is only at some intermediate point between these two extremes that a dilution will be found that gives the most successful differentiation between susceptibles and immunes. Theoretically, the best dilution to use is that which gives the greatest number of negative reactions when tested on convalescents, and which, conversely, will also disclose the largest number of positive reactors among susceptible individuals. But to determine this dilution is a problem of much difficulty, nor does it help matters to define it as a dilution of a certain strength, for such a statement gives no measure of its valency. It is a common experience that toxins prepared from the same strain of organism under experimental conditions which seem to be constant give wide variations in potency, so that a 1 in 50 dilution of one toxin may be equivalent to a 1 in 5000 dilution of another.

It follows, therefore, that until such time as the toxins used for a Dick test can be effectively standardised against an antitoxin constant and expressed in terms of this constant, it is premature to group individuals into positive or negative reactors, particularly as it has become customary to base this differentiation on the result of one solitary skin test. Until we have information regarding the effect of both higher and lower dilutions of the same toxin on the same group of individuals, we are unlikely to attain to a true interpretation of our results.

The experiments detailed in this report were undertaken with different dilutions of the same toxin, each individual receiving two, three, or four skin test doses together with a heated control. The toxin used is an 8-volume alcohol precipitated toxin. The smallest amount employed for a skin test dose is represented by 0·00015 mg. of the precipitated product, and from this starting point we have proceeded, by multiples of two, through a series of dilutions to a maximum skin test dose of 16 times the smallest—viz., 0·0024 mg. For descriptive purposes we propose to call the minimum dose one unit, so that the series of experiments we shall describe was undertaken with 1, 2, 4, 8, and 16 units.

Thus it has become possible to grade the individuals who have been tested into what may be termed "immunity groups," and also to determine how much excess of toxin is capable of breaking down resistance in such a way as to transfer a negative reactor into the group of positive reactors.

The most resistant group that comes within the ambit of our observations is composed of individuals who give no reaction with 16 units, while the most sensitive group is made up of individuals who react positively to one unit. The skin reactions of these extreme groups and of the intermediate groups are set forth diagrammatically in Table I.

TABLE I.

The classification of individuals into "immunity groups" according to their reactions to the toxin of *Streptococcus scarlatinæ*.

Group.	Toxin units.					Group.	Toxin units.				
	16	8	4	2	1		16	8	4	2	1
I. ..	–	–	–	–	–	IV. ..	+	+	+	–	–
II. ..	+	–	–	–	–	V. ..	+	+	+	+	–
III. ..	+	+	–	–	–	VI. ..	+	+	+	+	+

In our previous report[1] dealing with the preparation and precipitation of the toxin of *Streptococcus scarlatinæ* we divided individuals into positive and negative reactors, taking as positive reactions such as reached a diameter of 1 cm. or more, and classifying as negative all those of lesser extent. It soon became obvious to us, however, that although some slight reactions might be attributable to trauma yet many were actually positive, and therefore could not be legitimately classified as negative. With further experience it became possible for us to distinguish the reaction or disturbance due to trauma from the slightly positive reaction, and this latter we have designated by the symbol ±. The validity of establishing such an intermediate group between positive and negative reactors becomes apparent from a scrutiny of our figures, for with the two- or three-dose method of titration which we have employed it becomes possible to discern how, with increase in dosage, negative reactors are gradually transferred into positive reactors by passage through the intermediate ± zone.

There is also another type of reaction to which we would wish to draw attention. The Dick reaction as it occurs in susceptible folk is of a bright scarlet or pink colour, which to the experienced is unmistakable. In certain scarlet fever convalescents, and occasionally also in individuals who have not suffered from the disease, the reaction may be equal in area to a positive reaction, but it is either colourless or very faintly pink. Its presence may be detected only from the fact that it possesses a well-defined though very narrow pink edging or margin, which may be easily missed unless the examination be carried out in good daylight. From its appearance we would designate this as the "ghost" reaction, and we have classified it with the ± reactions.

(A) *Titration in Children.*

EXP. 1.—This was carried out with 1 and 2 units and was in the nature of a preliminary titration. Twenty children 14 of whom were from 2 to 5 years and six from 5 to 10 years of age, were tested intradermally. In none of these children as far as could be ascertained was there any history of scarlet fever. At the same time the same amounts of toxin were given to 20 adult females, hospital sisters and nurses, many of whom had had long contact with scarlet fever cases. These groups of individuals were chosen on the assumption that they were likely to represent extremes in so far as immunity to the toxin was concerned. The results, expressed in Table II., showed that although the amounts of toxin used gave good reactions in susceptible children, yet the doses employed did not disclose a single positive reactor among the adults.

TABLE II.

A two-dose experiment to show the differentiation between susceptible children and adult females.

	Toxin units.					
	1			2		
	+	±	–	+	±	–
Children (20) 2–10 years ..	12 ..	2 ..	6	12 ..	4 ..	4
Adult females (20)	0 ..	1 ..	19	0 ..	6 ..	14

EXP. 2.—In this experiment 2 and 1 units of toxin were used, the test being carried out on 25 non-scarlet children

and on 50 children convalescent from scarlet fever. The age-groups of these children were as follows:—

---

[1] Henry, H., Lewis, F. C., and Others: On the Toxin of *Streptococcus scarlatinæ*, THE LANCET, April 4th, 1925, p. 710.

Years—	2–5	5–10	10–15
Non-scarlet	20	5	—
Scarlet	13	27	10

The scarlet children were grouped according to their period of convalescence thus:—

Days—	0–10	10–20	20–30	30
Scarlet ..	0	3	7	40

The results (Table III.) show that with 2 units there is a marked preponderance of positive reactors among non-scarlet children and that the majority of scarlet convalescent children are resistant to the same dose.

TABLE III.

A two-dose experiment in selected children to show differentiation of normal from scarlet fever convalescent children.

	Toxin units.					
	2			4		
Children.	+	±	–	+	±	–
Non-scarlet (25)	16	6	3	20	3	2
Scarlet (50)	2	7	41	10	12	28

EXP. 3.—This was a three-dose titration carried out with 2, 4, and 8 units on 100 scarlet fever convalescents and on 100 non-scarlet individuals. Each series shows approximately 10 per cent. of adults, the remainder being children who, when classified according to their age, present two groups that are as closely parallel as is practically possible. The age-groups of both series and the period of convalescence in the case of scarlet fever individuals are as follows:—

Age-groups—	2–5	5–10	10–15	Adult
Non-scarlet (100)	40	32	19	9
Scarlet (100)	25	45	19	11
Convalescence in days—	0–10	10–20	20–30	30 on
Scarlet	5	22	24	49

The readings of this titration are set out in Table IV.

TABLE IV.

A three-dose experiment to show differentiation between non-scarlet children and scarlet fever convalescent children, as representing an average fever hospital population.

	Toxin units.								
	2			4			8		
	+	±	–	+	±	–	+	±	–
Non-scarlet (100) ..	53	7	40	55	13	32	64	19	17
Scarlet (100)	9	11	80	17	11	72	25	22	53

EXP. 4. *A Collection of "Throw-outs."*—In Exps. 2 and 3 we have dealt with two well-defined series of individuals. One of these series was made up of individuals who had passed through an attack of scarlet fever, while the other series comprised those who had passed through an attack of diphtheria. From the first series we have been careful to exclude those cases in which there was, on clinical grounds, doubt in regard to the diagnosis of scarlet fever and these we have grouped under the term "doubtful diagnosis." At the same time, there were found in the diphtheria wards a number of children in which there was a clear history of a previous attack of scarlet fever. These we have excluded from the non-scarlet cases and classified here as "old scarlets." The age-groups of these individuals are as follows:—

Age-groups—	2–5	5–10	10–15	Adult
Doubtful diagnosis (23).	3	12	5	3
Old scarlets (22)	2	14	5	—

The three-dose titration of these groups is given in Table V.

TABLE V.

A three-dose experiment in cases of doubtful diagnosis and in cases in which there is definite evidence of a previous attack of scarlet fever.

	Toxin units.								
	2			4			8		
	+	±	–	+	±	–	+	±	–
Doubtful diagnosis (23)..	10	4	9	16	3	4	18	2	3
Old scarlets (22) ..	1	0	21	1	0	21	2	5	15

EXP. 5. *Determination of End-points in the Scale of Titration.*—The figures which result from the titrations grouped together in Exp. 3 show the number of positive and negative reactions to 2, 4, and 8 units of toxin in two series of individuals, composed respectively of scarlet and of non-scarlet children of comparable age. There still remains for determination the number of positive reactors at the extreme limits of our scale—viz., with 1 unit and with 16 units. Ten scarlet fever convalescents who proved to be negative to 8 units were tested intradermally with 16 units, and of these five proved to be positive. No similar figures are available for non-scarlet children, but it may be assumed that in this case the number of positive reactors to 16 units is as before—viz., about half the number that is negative to 8 units. The 16-unit results are not easy to read, because here for the first time we found ourselves faced with the difficulty of pseudo-reactions. At the other end of the scale—viz., in experiments with 1 unit—it was found that out of 24 non-scarlet children who were positive to 2 units, 13 proved to be still positive to 1 unit. No figures are available in respect of scarlet convalescents, and here again we have assumed the number of positive reactors to 1 unit to be approximately half the number of those who are positive to 2 units. At this end of the scale also it is difficult to arrive at an accurate estimate, because the reactions are both slight in intensity and fugitive in character.

(B) *Titration in Adults.*

EXP. 6.—A three-dose test with 2, 4, and 8 units was carried out on 120 adult females and on 110 adult males, the result of the titration being set forth in Table VI. Of ten adult females who were resistant to the 8-unit dose, five proved to be still resistant to 16 units. In the case of the adult males no figures are available. Also, at the other end of the scale, in regard to the 1-unit dose no figures are available either in respect of adult males or of adult females. A reference to the graph shows that immunity is at a higher level in the females we tested than in the males.

TABLE VI.

A three-dose titration in adults.

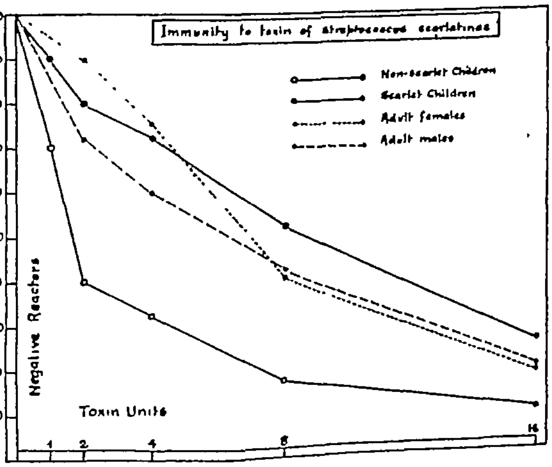
Adult males (110) .	25	5	80	31	12	67	40	23	47

Discussion.

Exps. 1 and 2 were undertaken with a view to determining how effective our toxin is in disclosing a differentiation between susceptibles and immunes. In each case there was a selection of individuals that resulted in an accentuation of this capacity for differentiation. The susceptible individuals were the most susceptible that could be found, and the resistant individuals were, on similar presumptive grounds, those whom we decided were likely to show the highest immunity. Therefore the differentiation between susceptible and resistant people is in each of these experiments at an exaggerated maximum.



On the other hand, the individuals grouped in Exp. 3 were not selected, and so represent better an average hospital population. From the figures obtained in Exp. 3 we have constructed a graph showing the degree of immunity of both scarlet and non-scarlet children at each point on our scale of titration. It is to be noted that the maximum amount of differentiation according to our experimental data is not at one particular point of the scale, but extends over a relatively large range of doses. With 2, 4 and 8 units it is practically 40, and it is perhaps of interest to note that the maximum percentage differentiation as given by the Dicks for one skin test dose is 41·0.

On reference to the theoretical definition of a skin test dose as propounded in the introduction to this Report it will be found that the 2 unit dose agrees more closely with this definition than any other, inasmuch as it gives the minimal number of positive reactors in scarlet fever convalescents. Yet the American skin test dose differs from our 2 unit dose in one very important particular, in that it discloses only negative or faintly positive reactors among scarlet fever convalescents, whereas the 2 unit dose gives positive reactions in 20 per cent. of convalescents. Most of these reactions are strongly positive, so that a difference of interpretation of readings does not account for the existence of this difference between our findings and those of American workers.

In seeking to discover what these positive reactors mean we would venture to suggest that the following considerations might be borne in mind. 1. They may be cases of mistaken diagnosis, a possibility which cannot be excluded. 2. They may be cases of scarlet fever which do not for some reason develop an immunity. It is to be noted that more than half these cases suffer from complications such as otitis, myocarditis, &c. 3. They may be cases which resemble scarlet fever so closely as to be clinically indistinguishable from it, in much the same way that paratyphoid resembles typhoid. In the present state of our information it is not possible to assign to each of these three considerations its proper measure of importance. We think it probable that no one of them can be altogether excluded.

There still remains to consider the question of the degree of immunity as shown by adults and by scarlet fever convalescents. To the graph which interprets Exp. 3 we have added our findings in regard to adult immunity. The majority of the females were hospital staff who were constantly coming into contact with scarlet fever, while the adult males were taken at random. Yet, except for an increased immunity in the females, there is but little difference between the two curves. Also we find that the level of immunity to which adults reach is practically the same as that attained by convalescent children. Of the males only 9 per cent. and of the females 20 per cent. gave a previous history of scarlet fever, so that the majority of the adults, both female and male, have acquired immunity without passing through a disease which is clinically recognisable as scarlet fever. Also, at first sight the degree of immunity reached by convalescent children would seem to be relatively low. Is this because the type of scarlet fever is at present mild in character, or is it because the peak of antitoxin production is reached only after months rather than weeks of convalescence?

PART II.

AN EXPRESSION OF INDIVIDUAL RESISTANCE IN TERMS OF ANTITOXIN CONTENT.

In the first part of this Report we have sought to classify individuals into a series of "immunity groups" according to their resistance to increasing doses of the toxin of *Streptococcus scarlatinæ*. Our findings showed that throughout any collection of individuals the resistance varied over a wide range. At one end of the scale of immunity could be grouped the majority of small children in that they proved to be sensitive to a small dose of toxin, whereas the bulk of convalescent scarlet fever children and the majority of adults either male or female were resistant to this dose. Further, by testing with multiples of this small dose it became possible to obtain a collection of folk who were highly resistant to the toxin in that they did not react to these higher doses.

It remained, however, to discover whether this resistance, as determined by a skin test, could be measured in any other way. The brief series of experiments detailed in this report shows that individual resistance to the skin test is correlated with the presence of antitoxin in the blood of the individual. The sera which have been proved to contain antitoxin were taken from individuals in Groups I. and II. of the "immunity groups" already mentioned. At the same time we have examined serum obtained from individuals in Groups V. and VI., and in these we have not detected any antitoxin which is measurable by the titration method employed.

Method of Titration.

The method has consisted in the mixing of a fixed amount of toxin with decreasing amounts of serum, the mixtures being incubated for one hour at 38° C. before inoculation. For example, if 50 units of toxin in 0·5 c.cm. of saline are mixed with 0·5 c.cm. of undiluted serum, and if 0·2 c.cm. of the mixture be used for the skin test, then the inoculum consists of 10 units of toxin and 0·1 c.cm. of serum.

For the testing of toxin-antitoxin mixtures individuals who are susceptible to 1 or 2 units have to be selected, because they react the most readily to any unneutralised toxin there may be in the mixture and so give a more exact end-point. The amount of toxin used in each individual dose of a toxin-antitoxin mixture is a matter for experiment. We have found that 4 units gives an end-point that is too indistinct, and that 20 units gives an end-point which occurs too suddenly, and which may occasion too large an area of skin reaction. A dose of 10 units has been selected, therefore, as being a practicable amount.

Interpretation of Readings.

The fact that these toxin-antitoxin mixtures are capable of dissociation after inoculation presents a problem which may add considerable difficulty in regard to the reading of an end-point. The phenomenon may be best explained perhaps by the description of an actual example. A human serum containing antitoxin was titrated against 10 units of toxin, the amounts of serum present in each skin test dose of the series being 0·1, 0·04, 0·02, 0·01, 0·004, 0·002, 0·001, 0·0004 c.cm. The reactions in the case of the first three doses were 0·25 to 0·5 cm. in diameter at 24 hours, and at 48 hours were faint and indistinct. In the case of the next three doses in the series the 24-hour readings gave areas of varying size from 1 to 2 cm. in diameter, whereas at 48 hours each of these areas had greatly increased by the formation of an areola, the total zone of skin affected being 3 cm. or more in diameter. In the case of the last two doses the reactions, of 2 to 3 cm. in diameter, were fully developed at 24 hours and had begun to fade at 48 hours. There are thus three zones of reactions to be read after the intradermal titration of a toxin-antitoxin mixture—a zone of complete neutralisation, a zone of dissociation and presumably of partial neutralisation, and a zone of no apparent dissociation with neutralisation at a minimum.

The problem of dissociation is not one that can be dealt with here, and we propose to discuss it more fully in a future Report, particularly as it has a distinctly practical bearing on the immunisation of individuals with toxin-antitoxin mixtures.

The end-point in the scale of titration which we have selected is the point at which occurs a reaction of 1 cm. or less in 24 hours. Each serum dealt with in this Report has been titrated on two or more individuals, the value given in each instance being the number of toxin units neutralised by 1·0 c.cm. of serum.

EXP. 7.—This was carried out with four sera taken from individuals who were strongly sensitive to toxin: Serum A, adult female, sensitive to 1 unit, giving no history of scarlet fever; B, child, aged 5 years, sensitive to 2 units, having no history of scarlet fever; C, child, aged 6 years, "doubtful diagnosis," sensitive to 2 units; D, adult female, aged 19 years, diagnosed as surgical scarlet fever, highly sensitive to 2 units. The results, set forth in Table VII., show that there is no neutralisation of 10 units of toxin even with 0·1 c.cm. of serum, and that if antitoxin is present it cannot be measured in the scale of titration used. The absence of dissociation in the case of serum A we are inclined to consider as indicating complete, or almost complete, absence of antitoxin, while its presence in sera B, C, and D indicates small quantities of antitoxin. Each of these sera, therefore, contains less than 100 units.

TABLE VII.

Four sera taken from individuals who are sensitive to small doses of toxin and titrated against 10 units of toxin. In all cases the reactions were more than 1 c.cm. in diameter.

Serum.	Test.	Serum—amounts in c.cm.			Serum.	Test.	Serum—amounts in c.cm.

Summary.

The sera of individuals who are sensitive to small doses of toxin contain little or no antitoxin. On the other hand, the sera of resistant individuals contain a measurable quantity of antitoxin, amounting to as much as 500 units. That this amount is considerable may be judged from the fact that the best of a series of horse antitoxic sera, the first to be produced in this country, titrated against 20 units of toxin, have given a unitage of about 800 on the same scale. The exact relationship of resistance to antitoxin content is a matter for further experiment.

There are peculiar difficulties which are inherent to an investigation of this nature. Fortunately we have had the encouraging help of the public health committee of the Birmingham City Council, and it gives us pleasure to record our appreciation of the facilities they have given us in affording access to clinical material in the City Fever Hospitals and of the practical and friendly interest they have taken in the progress of the work. The majority of the reactions herein detailed were carried out by ourselves, and for most of the remainder we have to thank Dr. E. H. R. Harries and his medical officers. We gladly express our thanks, too, to Dr. R. H. H. Jolly and Dr. B. C. Haller, of Wolverhampton, together with Dr. J. B. Ferguson and Dr. R. Sandilands, of Smethwick, who generously placed at our disposal the available material in the respective hospitals over which they have control. We also wish to thank the President and members of the Birmingham Rotary Club for assisting us in obtaining the necessary number of adult volunteers for test.

THE GEOGRAPHICAL DISTRIBUTION OF HEART DISEASE IN ENGLAND AND WALES

AND ITS RELATION TO THAT OF ACUTE RHEUMATISM AND TO SOME OTHER FACTORS.

BY MATTHEW YOUNG, M.D. GLASG.

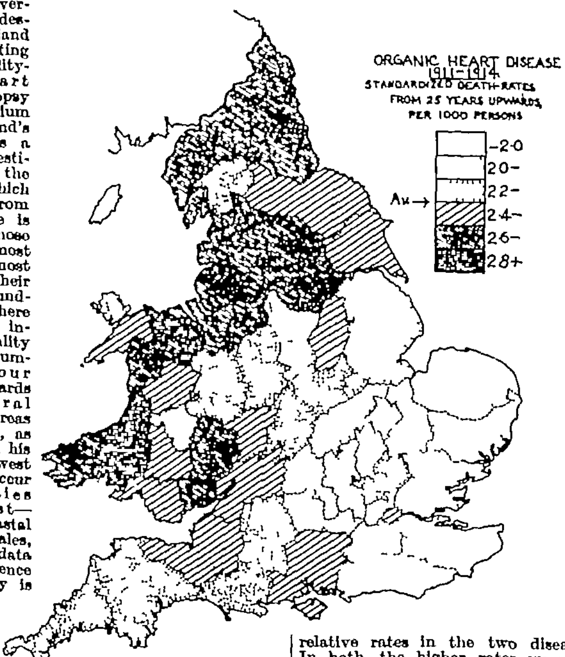
(*From the National Institute for Medical Research.*)

THE annual mortality from heart disease in England and Wales comprises a relatively large proportion, approximately 12 per cent. on the average, of the mortality from all causes. It seemed to be of interest to determine from recent data if the mortality from this cause showed any notable variation in different parts of the country, if the districts with high and low rates of mortality were distributed in any special manner, and if the geographical distribution of heart disease had any relationship to that of acute rheumatism which so frequently precedes it, or any association with special physical features, or industrial or environmental conditions.

The data that were used were the recorded deaths, at the different ages, from heart disease in the administrative counties and county boroughs of England and Wales published by the Registrar-General in his annual reports. Two groups of data were taken: (1) The deaths from organic heart disease in the four years' period 1911–14, and (2) the deaths from heart diseases in the three years' period 1921–23. Included in the term "organic heart disease," as defined by the Registrar-General, are valvular disease of the heart, fatty degeneration of the heart, and other organic diseases of the heart. The data for the three years' period consist of heart diseases in the aggregate and include, in addition to organic heart disease, pericarditis, acute endocarditis, acute myocarditis, and angina pectoris. These other diseases only comprise, however, as shown by the data for the three years' period 1921–23, approximately 6·5 per cent., and, excluding angina pectoris, 4 per cent. of the total deaths from heart disease on the average. Amongst the recorded deaths from heart disease in the same triennial period, 44 per cent. are described definitely as valvular disease, a further 20 per cent. are given as "heart disease undefined," which is probably also to some extent valvular disease; well over 50 per cent. of the registered mortality from heart disease may thus probably be attributed to valvular affections.

From the published data for deaths from heart disease in urban and rural districts in the administrative counties and the associated county boroughs, figures were compiled for the areas corresponding approximately, but not accurately, to registration counties, and for each of these standardised death-rates from heart disease for the sexes separately, and for persons from 25 years of age and upwards and from 45 years and upwards respectively were calculated. These standardised death-rates for the different areas, which may be referred to briefly as county areas, were used as an index of the mortality therein. In England and Wales data were available for 55 counties altogether.

The standardised death-rates from heart disease amongst persons from age 25 and upwards were inserted in a map of England and Wales (see figure) showing the counties, and the distribution of the rates obtained from the data for the two periods, 1911–14 and 1921–23, was in general very similar and very characteristic. The death-rates for the earlier period are shown in Table I., and the distribution of these rates, classified in six different grades of magnitude, is shown in the accompanying map. The highest rates, with few exceptions, are found localised in the northern and western areas of the country; in the counties of Wales particularly, the rates are generally above the average for England and Wales as a whole. The counties of Radnor and Westmorland are notable amongst the exceptions to this generalisation. The rate in Westmorland, however, is practically the average for the whole country, and in the later period it exceeds the average. It should be recollected also that in both these counties the number of deaths and the total population are relatively small, and consequently the death-rates have a larger probable error than in many of the other counties. In the eastern, south-eastern, and midland counties of England, however, the mortality rates are lower than in the counties farther west, and definitely below the average as a rule. The incidence of the relative mortality thus shown is very divergent from that described by Haviland (1875) as existing for the mortality-rates for heart disease and dropsy in the decennium 1851–60. Haviland's conclusion, as a result of his investigation, was that the counties in which the mortality from heart disease is greatest are those that are the most inland or the most protected by their physical surroundings, and that there is a progressive increase of mortality from the circumference of our peninsula towards its more central localities. Whereas Haviland found, as he illustrates in his maps, the lowest mortality to occur in the counties farthest west—namely, the coastal counties of Wales, in the present data the highest incidence of mortality is localised there. The discrepancy may be explained in part by Haviland's use of crude mortality rates for the earlier period, but the distribution of relative mortality in the two periods, 1851–60 and 1911–14, is so completely at variance that it seems unlikely that this can be an adequate explanation. Possibly some change in the relative incidence in different districts may have taken place in the interval that has elapsed between the two epochs. It is readily apparent from the map that the lowest mortality in the present data is not coincident with or closely related to the greatest exposure to prevailing winds or sea air, or the highest mortality characteristic of districts that are protected by their physical features, as suggested by Haviland, and that other factors that determine the distribution must be in operation.



Association between Relative Mortalities from Heart Disease and Acute Rheumatism.

The question then arises, is there any correspondence in the county areas between the distribution of the relative mortalities from heart disease and acute rheumatism? In a previous paper (1921) on the epidemiology of rheumatic fever, the distribution of the mortality from rheumatic fever in the registration counties of England and Wales, as shown by the standardised death-rates from age 15 upwards, is given for the decennium 1901–10. This analysis seemed to show that an excessive incidence of the disease in the counties had some definite relation to excessive amounts of rainfall and cold weather. Though the standardised death-rate from rheumatic fever can only be regarded as an approximate measure of the actual incidence of the disease in the respective counties, it is the only criterion that is available at present. The use of the mortality rates as an index of the prevalence of the disease in different districts receives some support as regards the northern, western, and eastern counties of England from some data recently published in an analysis of the incidence of rheumatic fever amongst insured persons in England and Wales in 1922 by the Rheumatism Committee of the Ministry of Health. An excess of acute, including subacute, rheumatism over what might be expected was found in the north-western and north-eastern divisions, whereas the south-eastern division showed a pronounced shortage as compared with what might be expected.

On comparing the two maps of England and Wales that had been prepared to show the mortality-rates from rheumatic fever and from heart disease in the respective counties, evidence of some agreement in the distribution of the relative rates in the two diseases was apparent. In both, the higher rates were found in general in the northern and western counties; in the eastern counties, as has already been mentioned for heart disease, the rates were considerably lower. The data available made it possible to determine the relationship more precisely. Coefficients of correlation were calculated between the standardised death rates from rheumatic fever amongst persons aged 15 and upwards in the respective counties in the decennium 1901–10 and the standardised death rates from organic disease of the heart in the corresponding counties for each of the periods 1911–14 and 1921–23. In the earlier period, the coefficient of correlation between the death rate from heart disease at age 25 and upwards and acute rheumatism was + 590 ± ·059 and that between the death rate from heart disease at age 45 and upwards and acute rheumatism + 573 ± ·061. For the later period the coefficients of correlation between the corresponding variables were ·608 ± ·057 at age 25 and upwards and + 503 ± ·063 at age 45 and upwards—i.e., practically identical with those for the earlier period. A very definite association thus exists in the counties between the distribution of the relative mortalities from rheumatic fever and diseases of the heart in the aggregate.

The Industrial Factor.

With regard to the distribution of relative mortality from heart disease throughout England and Wales, certain other points require consideration. Amongst the English counties showing the highest mortality-rates from heart disease are the West Riding of Yorkshire, Durham, Northumberland, and Lancashire. These counties possess the common feature that one or two special industries provide occupation for a relatively large proportion of their inhabitants. Thus, in the West Riding, textile, principally wool and worsted, manufacture and coal-mining; in Lancashire textile, principally cotton, manufacture, coal-mining, and working in metals; in Durham and Northumberland, coal-mining, are much the commonest forms of employment for males. It may be suggested that the excessive mortality from heart disease found in these counties has some relationship to the special industries that prevail therein. The influence of occupation in determining the onset of heart strain and valvular disease of the heart has been described by some authors, including Peacock (1865) and Cowan (1922). Fortunately it is possible to obtain some information on this point. In the supplement to the seventy-fifth annual report of the Registrar-General, Part IV., are given particulars of the mortality from valvular disease of the heart in certain occupations in the three years 1910, 1911, and 1912. The comparative mortality figure for valvular disease of the heart for all occupied and retired males in the three years' data is 39. In textile workers as a whole and in those engaged in cotton manufacture, in wool and worsted and in hosiery manufacture, the mortality figures for the disease are practically the average for all males. In the coal-mining industry as a whole the comparative mortality figure for valvular disease of the heart is 37; in coal-miners in Lancashire and in Northumberland and Durham it remains at the same level—i.e., approximately the average for all occupations. In the groups of metal workers the comparative mortality figure for the disease is usually under the mean value. The mortality-rates for valvular disease thus do not seem to be in excess in the occupations which provide the major proportion of the employment in these counties. Further, as has been mentioned already, many counties with relatively high death-rates from heart disease as a whole, including those actually highest, are found in Wales. In Brecknock, Carmarthen, Denbigh, and Glamorgan a relatively large proportion of the male population is employed in the mining industry, but in Cardiganshire and Pembrokeshire, where rates amongst the highest that occur are found, the population is mainly engaged in agricultural pursuits; in Merionethshire also, agriculture provides employment for the largest proportion of the male inhabitants, though many are engaged in slate-mining and quarrying. In slate-quarriers and workers the comparative mortality figure for valvular disease of the heart is 37—i.e., practically the average; in agricultural workers and farmers the comparative mortality figures are definitely lower than the average for all occupied males. The circumstance that the highest death-rates from heart disease occur in counties in Wales where no specially adverse industrial conditions exist, such as obtain in the West Riding of Yorkshire and Lancashire, is opposed to the view that the excessive prevalence of the disease in the latter can be attributed in any definite degree to occupational influences.

Incidence of Heart Disease in the County Boroughs.

Some reference may be made to the incidence of heart disease in the county boroughs. As the deaths at the different ages in the several county boroughs had been extracted for the purpose of summation with those in the administrative counties with which they are associated, and as the corresponding populations were readily obtained, the standardised death-rates from age 25 and upwards were calculated for each borough. The standardised death-rate from organic heart disease amongst persons in all the county boroughs taken together exceeds that for England and Wales as a whole by 9·5 per cent. and that for the rural districts of England and Wales by nearly 18 per cent. Dr. J. Brownlee (1922) has shown, however, that the apparent excess in mortality from valvular heart disease in town over country practically disappears when the life table death-rate is used as the criterion. In the data for the four years' period 1911–14 (see table) the standardised death-rates from heart disease in the different county boroughs show a considerable range of variation. The highest values are found in Bury, South Shields, Oldham, West Hartlepool, Chester, Rochdale, and Worcester. Though these include some of the chief industrial county boroughs of Lancashire, Durham, and the West Riding of Yorkshire, and though other industrial boroughs of these counties show relatively high values, certain other boroughs therein—e.g., Sheffield, Wigan, and Bolton, in which industrial activity is apparently quite as intensive as in those already named—have relatively low mortalities from heart disease. Moreover, the cities of Chester and Worcester are two boroughs in which the mortality-rates from heart disease are amongst the highest that are found, and they are not pre-eminently industrial. From this it would appear that, though the environmental conditions that are associated with great intensity of industrial activity may have some influence in determining the incidence of heart disease, it cannot be said from the present data that an excessive mortality from this cause is a feature in all the boroughs that may be described as industrial.

Conclusions.

From the data that have been investigated, it seems reasonable to draw the following conclusions:—

1. The mortality from heart disease in the counties of England and Wales shows quite definitely a tendency to a special distribution in which the higher death-rates are found in the counties towards the west.

2. The geographical distribution of the relative mortalities in the periods examined is very different from that described by Haviland as occurring in data for an earlier epoch, and the explanation offered by him—namely, that the excessive incidence is found in counties that are distant from the sea and sheltered by their physical surroundings from the sea winds, cannot be held to account for the distribution of the fluctuations in incidence in the present data.

3. A definite association exists in the counties between the distribution of mortality from organic heart disease and heart diseases in the aggregate and the mortality from acute rheumatism. The relative incidence of acute rheumatism appears to be the essential factor that determines the incidence of heart disease, although other factors, possibly mainly environmental, may have some influence on the rate of mortality in different districts.

THE THERAPEUTIC PROPERTIES OF STOVARSOL

(ACETYLAMINOPHENYLARSINIC ACID, "190").

BY C. LEVADITI,
OF THE INSTITUT PASTEUR, PARIS.

THE acetyl derivative of amino-oxy-phenylarsinic acid, first introduced into therapeutics in 1922, possesses such interesting curative and preventive properties that it has seemed to me to be of sufficient importance to warrant a review of the question to the point to which it has now developed. I shall first outline the facts relating to the discovery of the parasiticidal properties of stovarsol, and then review the results obtained with this product in syphilis, yaws, malaria, *amoebiasis*, and other intestinal parasitic infections.

Historical.

Acetylaminophenylarsinic acid was first prepared in Germany by Ehrlich, Benda, and Bertheim,[1] but the compound was not systematically examined by these authors. As a matter of fact, it belongs to the series of arsenical compounds known as "arsinic acids," in which the arsenic is pentavalent, and Ehrlich considered the members of these series quite inferior to the "arsenobenzenes," in which the arsenic is trivalent. However, in 1922, Fourneau,[2] at the Institut Pasteur, decided to re-investigate the arsinic acids, believing the unsatisfactory results obtained in Germany to be directly attributable to the presence of certain impurities which the compounds of these series are apt to contain. Fourneau, and his co-workers Mr. and Mme. Trefouel, re-prepared almost all the members of the series, carefully purified them, and then tested them on both animals and human beings, injecting them either intramuscularly or subcutaneously. Tests were carried out with amino-oxy-phenylarsinic acid ("189") and stovarsol ("190") in experimental syphilis by Levaditi and Navarro-Martin,[3] and in human syphilis by L. Fournier and his co-workers, Guenot and Schwartz.[4] The results obtained in human syphilis were very interesting; however, in view of the fact that relapses were observed, the product, thus administered, did not seem to have an action comparable to that of the arsenobenzenes.

Such was the condition of affairs when, following their studies on the action of bismuth compounds, Sazerac and Levaditi[5] demonstrated the value of a prophylaxis of syphilis by the simple ingestion of an efficient spirillicidal compound, a method in itself more practical than injections or local applications of pomades. The experiments carried out with soluble bismuth salts (lactate) administered by the mouth having failed to give very encouraging results, Levaditi and Navarro-Martin[6] then tried the arsenicals. Inasmuch as they had already tested acetylamino-oxyphenylarsinic acid in subcutaneous injection, they used the same compound, prepared by Mr. and Mme. Trefouel according to Fourneau's directions, and this time they administered it by the mouth.

The experiments were undertaken first from the prophylactic and then from the curative standpoint. The first observations showed that stovarsol exerted, in man as well as in small animals, a distinct prophylactic and curative action in syphilis. These were completed by numerous and convincing clinical observations by Fournier and his co-workers. Thus was inaugurated the introduction into the therapy of syphilis of an arsinic acid administered by the mouth. In what follows we shall see to what an extent this therapy has developed.

General Considerations.

It is quite proper to ask, at this juncture, if indeed this new therapy offers any advantages over the older methods of administering arsenical compounds. From the very beginning of their work, Levaditi and Navarro-Martin noticed that, when given by the mouth in experimental syphilis, stovarsol was more active than when injected under the skin or into the muscle. At the same time they remarked that its toxicity was greater in the first case than in the second. (In this connexion cf. the clinical observations of Fournier and his colleagues, and the recent researches of Navarro-Martin and of Kolle.[7]) How was this surprising fact to be explained? Very probably the compound undergoes in the intestine or in the liver certain modifications more favourable to its therapeutic action than the changes which take place in the other tissues or in the general circulation. The intestinal tract, then, is more favourable to the development of the therapeutic effects of stovarsol, and this is a distinct advantage. Again, it often happens, in practice, that it is impossible to treat syphilitic patients by the injection (even intramuscular) of any spirillicidal compound whatever. It may also be necessary with some patients to give a supporting treatment during the interval between two series of arsenic or bismuth injections. Such a treatment is easily given with stovarsol. These constitute serious arguments in favour of this new therapy per os.

Let us now examine briefly what we know of the results obtained with stovarsol in syphilis, and in other diseases such as yaws, the intestinal parasitoses, malaria, and, in fact, wherever the use of this compound has afforded an opportunity of collecting interesting data.

1. *Stovarsol in Syphilis.*

Besides the first experiments of Levaditi and Navarro-Martin, referred to above, particular attention should be called to the work of Fournier and his co-workers, Levaditi, Navarro-Martin, and Schwartz.[8] These authors treated 80 syphilitic patients by ingestion of stovarsol in the form of tablets containing 0·25 g. Four tablets, representing a dose of 1 g., were given every morning in a little water before breakfast in periods of from five to seven days, each period being followed by an interval of equal length. In this way a total dose of 12–16 g. of stovarsol was given the first month. This method of administration was decided upon with two ideas in view: First, better arsenical impregnation, and second, prevention of accumulation. (Mr. and Mme. Trefouel had previously demonstrated that the elimination of the arsenic, which is abundant during the first two or three days, decreases very considerably on the following days.)

According to these authors, stovarsol exerts, in a great number of cases, a remarkable action on the primary, secondary, and tertiary erosive and ulcerous lesions, an action which is often as rapid as that of the arsenobenzenes given intravenously. The product induces a rapid healing of the superficial syphilitic lesions; it is capable of arresting the evolution of the disease and of exerting a favourable effect on the blood reaction. As a matter of fact, Fournier and his co-workers have published a number of serological curves in which are shown either the rapid negativation of a sero-reaction which was strongly positive at the beginning of the treatment, or the maintenance of a negative Wassermann in cases where the treatment with stovarsol was begun in the pre-serological period. To this must be added the excellent tonic effect which the compound exerts on the general condition of the patients. Naturally enough, as with every other arsenic compound, there will be encountered some cases both of arseno-resistance and of relapse. For this reason, Fournier and his fellow-workers look upon stovarsol as a weapon to be used in attack either alone or in association with another specific such as bismuth. "The benefit of the absorption of '190' (stovarsol) per os is absolutely real in every case where, for any reason whatsoever, intravenous or subcutaneous injections of antisyphilitic medicaments are impracticable."

The results of these researches have been generally confirmed by several authors in France as well as in Germany. In France, Yovanowitch,[9] in a noteworthy thesis, declares that stovarsol has a marked antisyphilitic power, comparable with that of the arsenobenzenes and the salts of bismuth. Its action is directed, however, very much more against the infectious cutaneous and mucous lesions, which it sterilises, than against the serological reactions, which it influences more slowly than either bismuth or the arsenobenzenes. Thus, whereas in some cases the author has recorded a total negativation of the Wassermann, in others there was only a marked attenuation of the reaction. However, the author himself recognises that the treatment with stovarsol was never very intensive. "It is logical to think," says Yovanowitch, "that with stronger doses the stovarsol would have exerted a deeper action on the evolution of the syphilis, and would have more strongly influenced the Bordet-Wassermann reaction."

Again, Cadenaule and Clarac [10] report evidence to show that hereditary syphilis is susceptible of being treated efficaciously by stovarsol. One of their observations is to the effect that stovarsol, given half an hour before feeding, is perfectly tolerated by the new-born, that there is advantage in administering high doses (0·12 g. per day for a child weighing 3 kilos), and that the results are most satisfying: disappearance of the cutaneous lesions and of the coryza, marked general improvement, and increase in weight.

In Germany we would call attention to the work of Oppenheim, of Heymann, and of Weitgasser. The first-named author [11] finds that stovarsol administered per os acts in a manner which is rigorously specific even in a dose of 0·25 g. He gives six observations in support of this view. The product acts on the syphilitic lesions and the treponema quite as strongly as mercury, bismuth, or salvarsan. In a second and longer report,[12] Oppenheim describes a large number of observations which permit him to form the conclusion that no other antisyphilitic agent given per os exerts as marked a therapeutic action as stovarsol, which, when properly administered, is perfectly well tolerated by the patients. Its influence on the treponema and upon the specific lesions is comparable with that of the arsenobenzenes; moreover, it determines an increase in weight. Apparently relapses are rare, for Oppenheim reports only two out of the 83 cases treated.

The indications are hypersensitiveness to salvarsan, difficulty of giving intravenous injections, impossibility of applications other than per os, replacing salvarsan in its association with mercury or bismuth. According to Oppenheim, the treponemata disappear in 24–48 hours, the primary lesions heal in 5–15 days, while the eruptive manifestations of the disease disappear in a few days.

The conclusions of Heymann [13] are very similar to the above. They show that stovarsol is perfectly tolerated [14] even when given in daily doses of 1 g., and a total dose of 20 g. in a month. The author believes that this compound is, at the present time, the most active antisyphilitic agent which can be given per os. It has a most satisfactory action on all of the ordinary manifestations of syphilis, and exerts a favourable influence on the Wassermann reaction. Heymann is likewise of the opinion that stovarsol can be administered in conjunction with bismuth or mercury. Weitgasser [15] is more reserved in his opinion. He recognises the manifest spirillicidal action of the new product, but has not so far observed any profound and lasting effect on the Wassermann. The question may be asked, however, whether, in the cases treated by Weitgasser, the treatment was sufficiently intensive.

From the foregoing, the basis for the use of stovarsol as an antisyphilitic seems firmly established. In our own opinion, the new medication is applicable to the rapid sterilisation and healing of the specific lesions, whatever they are; in other words, it constitutes a method of curative prophylaxis of which the advantages cannot be overrated. If, in a great many cases, treatment exclusively by stovarsol is sufficient to determine healing of the lesions and to render the Wassermann persistently negative, in other cases it is necessary to associate with stovarsol another powerful specific drug, having a somewhat deeper and more durable action, such as bismuth. The advantages of an arsenical treatment with stovarsol lie in the spirillicidal strength of the compound, the ease with which it is administered, and its general tonic action on the whole system.

2. *Stovarsol in Yaws.*

Yaws, the ulcerous disease caused by *Spirochæta pertenuis* (Castellani), responds, like syphilis, to treatment with stovarsol. This has been demonstrated by the recent work of Beurnier and Clapier,[16] who report excellent results. They recommend doses not exceeding 1 g. in 24 hours, an entire cure requiring 8 g. for an adult weighing 50 kilos. Baermann[17] has studied the preventive action of stovarsol in yaws, and has observed that the compound given in a total dose of 3·75 g. in four days is capable of protecting man from a massive infection. He reports similar results with monkeys. Tanon and Jamot [18] remark that stovarsol cures the lesions of yaws even when they have proven resistant to the arsenobenzenes. They further observe that children seem to tolerate the product as well as adults, that it is advantageous to administer stronger doses at the beginning and to reduce them later, and, finally, that the fact that its administration by the mouth makes it very acceptable to the natives, who exhibit a certain apprehension of injections in general, of whatever sort.

To close this chapter on the spirillary diseases curable by stovarsol, let us simply mention intestinal spirochætosis (Waldorp [19]), ulcero-membranous stomatitis (Sabrazes [20]), spirillary bronchitis (Fontanel [21]), (Couvy [22]), phagedenic ulcer (Couvy [23]), Vincent's angina (Couvy [24]), (Cot [25]), &c.

3. *Stovarsol in the Intestinal Parasitoses.*

Ravant [26] was the first to use arsenicals by the mouth in the treatment of intestinal amœbiasis. He used the arsenobenzenes for this purpose, and stated the facts in favour of this method. But it is to Marchoux [27] that we owe the discovery of the parasiticidal and curative action of stovarsol in amœboid dysentery and intestinal lambliasis. In two papers published in 1923 he reported the first results obtained with stovarsol in the treatment of these diseases. His observations have been confirmed by Delanoe,[28] Leger and Nogue,[29] Fontanel,[30] Rubenthaler and Jansion,[31] Leon Bernard and Thomas,[32] and still more recently by Petzetakis.[33] Marchoux has recently published [34] a review of the results obtained, and we cannot do better than to give a summary of his paper at this point.

Amœbiasis.

Between March, 1923, and July, 1924, Marchoux treated by means of stovarsol 50 patients infected with *Amœba dysenteriæ*. The infections had been obtained in France, Germany, Orient, Morocco, Syria, and in the French Colonies. Of these 50 patients, all but two were very successfully treated. Of these two, the first had a dysentery which resisted every treatment tried, while the second showed improvement only while the treatment was in progress. In all the other cases the amœba and the cysts disappeared on the second or third day, while the quantity of stools diminished and their consistency became firmer. In addition, there was a general improvement in the general health of the patients, and a subsiding of the secondary effects of the infection. In order to avoid any possibility of relapse, Marchoux recommends a supporting treatment of two tablets a day (0·50 g.), the medicine being taken regularly at meal-time for six weeks. Certain dietary precautions are also recommended: complete abstention from tobacco, from all alcoholic beverages, and from fresh butter.

Petzetakis, of Athens, has treated with stovarsol a number of cases of intestinal amœbiasis, lambliasis, and diarrhœa due to various species of trichomona, and comes to the following conclusions. Stovarsol is an excellent remedy for the intestinal parasitoses. The compound destroys the amœba, and in some cases its favourable action is evident during the first 24 hours of treatment. There are some cases, however, which prove resistant or which relapse. He suggests that in these cases the dosage be increased or the treatment prolonged. The treatment is applicable to children as well as to adults. Finally, Petzetakis insists upon the fact that stovarsol exerts a *preventive* action against infection by *Amœba dysenteriæ*, and mentions a case in support of this contention.

Lambliasis.

Marchoux [35] has treated 21 cases of intestinal lambliasis, with diarrhœa and presence of lamblia in the fæces. Treatment with stovarsol produced an immediate improvement, and, even with small doses, the cysts disappeared from the fæces. In some cases, however, the cysts reappeared if treatment was stopped completely. A supporting treatment of 0·25 g. (one tablet) of stovarsol per day is therefore recommended. According to Marchoux [36] stovarsol always destroys the blastocysts, which are the cause of the persistent diarrhœa.

Malaria.

If, on the one hand, Baermann (loc. cit.) was unable to obtain a preventive action in tertian malaria by using stovarsol as a prophylactic agent, on the other hand, Valenti and Tomaselli [37] have called attention to the efficacy of the product given per os in tertian and quartan fever. In a short paper, which appeared last September, these authors cited a case of malaria (quartan type), with repeated accesses of fever extending over a year, which had resisted intensive treatment with quinine. Plasmodia were present in the blood-stream. Treatment was begun with stovarsol (one tablet the first day and two tablets each day following). There was a single access of fever after beginning the treatment and no relapse, although the patient was observed for more than a month afterward, and in spite of the fact that the stovarsol was discontinued on the eleventh day. The plasmodia disappeared from the blood-stream on the sixth day. The second case was similar to the first except that it was of the tertian type.

Independent of Valenti and Tomaselli, Marchoux and Cohen [38] have studied the action of stovarsol in tertian malaria in general paralytics intentionally infected (method of Wagner). Seven patients were treated by intravenous injection of a solution of the sodium salt of stovarsol. The product seemed active to the extent that the attacks of fever ceased and the parasites disappeared from the blood-stream. In a second paper, Marchoux [39] describes the results of experiments undertaken with 130 malarial patients at Marengo, Algeria. The treatment consisted of the ingestion of 1 g. of stovarsol per day, or the intravenous injection of a similar quantity of its sodium salt. Marchoux concluded that stovarsol is effective against *Plasmodium vivax*, but does not seem to be very active against either *Plasmodium malariæ* or *Plasmodium falciparum*.

Although these observations are still not sufficiently numerous to permit the formulation of definite conclusions, it would appear that stovarsol, either given per os or by intravenous injection of its sodium salt, acts on malaria causing the disappearance of the parasites and a suppression of the accesses of fever. It will be for further research to show whether or not certain forms of malaria respond to this treatment, and whether or not the curative action is lasting. In any case, these researches will be of particular interest.

Conclusion.

Starting with a study of the prophylaxis of syphilis by way of the mouth, the field of action of stovarsol has become, in a very few years, greatly enlarged. One after the other, the treatment of syphilis, of yaws, of spirillary infections in general, of amœboid dysentery, of intestinal lambliasis, of the blastocystic diarrhœas, and, very probably, of malaria also have benefited by this new arsenic compound or rather by this new method of treatment per os. The efficacy of the method, its exceeding simplicity, and the security which it gives in a multitude of circumstances render it worthy of the attention of medical men, who, in their turn, are called upon to pass judgment upon it without any preconceived ideas, as is always proper when it is a question of controlling the observations made by conscientious workers.

Clinical and Laboratory Notes.

A CASE OF LUMINAL POISONING.

By HILDRED CARLILL, M.D. CAMB., M.R.C.P. LOND.,
PHYSICIAN TO WESTMINSTER HOSPITAL.

THE following case of poisoning with luminal is probably worthy of record, for the symptoms, although alarming at the time, were followed by complete recovery.

A sober woman of 69, in collision with a cyclist on Nov. 24th, 1924, received a blow on the back of the head which momentarily stunned her. She found her way home and at once exhibited evidence of mental impairment. For example, she filled hot-water bottles with cold water, and next morning came downstairs with fish knives in her hair and proceeded to pour out tea into the milk jug. The sphincters were uncontrolled.

She was admitted to hospital on Dec. 1st, garrulous, incoherent, confused, and incontinent. There was an unclean scalp wound over the occiput in the middle line. There was no evidence of fracture, intracranial hæmorrhage, or defect of the visual apparatus, but the left pupil was larger than the right. There was no aphasia or paresis, and there was no sign of affection of the motor or sensory pathways. The systolic and diastolic blood pressure measured 140 mm. and 80 mm. of mercury respectively. The serum and cerebro-spinal fluid were healthy.

By Dec. 24th her symptoms had somewhat abated and the sphincters were controlled. She was still restless, garrulous, and confused. Luminal and potassium bromide in small doses were prescribed but, inadvertently, gr. 10 of the former and gr. 50 of the latter were administered daily for 12 days (total luminal gr. 120, potassium bromide gr. 600). On the twelfth day, Jan. 4th, 1925, she became stuporose and had a recurrence of double incontinence. The pupils were much contracted and lost their reaction to light. At times there was a divergent squint. The pulse-rate was increased. The cerebro-spinal fluid was under normal pressure. The urine contained no hæmatoporphyrin. After stimulation and a long delay she feebly obeyed certain instructions. Energetic treatment was employed in the form of strychnine, hot coffee by mouth and rectum, oxygen, and faradism. The luminal and bromide were cancelled. For a few days the periods of mental alertness increased in length but on each occasion she relapsed rapidly into stupor. Her conversation showed extreme confusion of thought. The tendon and superficial reflexes were unaffected throughout. By Jan. 10th the urgent symptoms were relieved and the sphincters once more under control. The systolic blood pressure measured 120 mm. of mercury. The pupils remained unequal and reacted to light very sluggishly. Then followed a period of four weeks in which she was greatly confused. On Jan. 19th, for example, her answers to questions were as follow. Year ?—March. Age ?—59. Year of birth ?—1950. Age ? —Westerham. War ?—China versus Chilians. Her handwriting was illegible and her composition grotesque. She knew not where or who she was. She expressed a fear of being killed by a firing party, and she said that her sister had fallen into a basket of damsons and, not being a business woman, would lose her money. She saw pistols in the hands of other patients and said that they wore leather helmets as a precaution against being killed. Her intelligence, judged by the accuracy of her replies to questions, varied from hour to hour. Rarely could her attention be secured.

On Feb. 10th Dr. H. J. Norman saw her with me and found her depressed and anxious, readily confused, and unduly apprehensive. The next day she rushed screaming round the ward and refused to be pacified until the windows, which had been closed for the round, were reopened. On Feb. 12th she made a sudden and complete recovery and her memory for the recent and distant past was once more clear.

Convalescence has been uninterrupted. She went to the seaside on March 5th, and recently I have had from her a grateful letter of a woman in complete possession of all her faculties. I call attention to the amount of the drugs taken, the value of faradism in treatment, and the avoidance of certification.

A CASE OF
RENAL GLYCOSURIA WITH KETONURIA.

BY J. PATTERSON, M.Sc., PH.D.
(*From the Biochemical Department, Charing Cross Hospital.*)

WHILE the crucial means for distinguishing between diabetes mellitus and renal glycosuria lies with the sugar-tolerance test, it is generally recognised that confirmatory to a normal curve indicating renal glycosuria is a urine examination showing a fairly constant and low value for the percentage of sugar, with the complete absence of acetone bodies. A negative finding with regard to these latter substances is such an invariable result in this type of case that one might have assumed reasonable certainty in diagnosing diabetes wherever an obviously positive glucose test was accompanied by an authentic acetone reaction in the urine. In only one case of renal glycosuria so far described (Allen, Wishart, and Smith, 1919,[1]) have ketone bodies been detected, but then only at the time the patient was admitted to hospital, for when placed on full diet the acetone test immediately became negative.

It would seem, therefore, to be of interest to supply a few details pertaining to a case which was quite exceptional in that the urinary examination was apparently contradictory to the findings based on blood analysis.

Clinical Record.

The patient, a man aged 42, was admitted to hospital with a history suggestive of pulmonary tuberculosis and diabetes.

History.—In 1911 he underwent an operation for gastric ulcer, at which time he was discovered to have sugar in the urine and was evidently regarded as diabetic. Later, he attended a hospital as an out-patient for six months, being told to diet carefully. Towards the end of 1918 he developed a bad cough, afterwards began to have night-sweats, and also brought up dark-coloured sputum. He had dyspnœa on exertion and suffered from loss of strength. Going before a medical board, he was X rayed and phthisis suspected, but shortly afterwards the cough improved and the night-sweats ceased. During the last six months preceding admission, dry red rashes appeared on the left thigh, both forearms, and scrotum. He had been thereupon examined at a skin hospital, where it was believed his skin disease was related to a diabetic condition.

No evidence of active pulmonary tuberculosis being found, a brief inquiry into his "diabetic" condition was instituted, with the results recorded below.

Chemical Findings.

1. *On full diet.*—Sugar and acetone constantly present in the urine, former identified as glucose in the form of phenylglucosazone ; amount varying from 0·5 to 3 per cent. ; latter confirmed by Lieben and by Gunning tests after distillation.

	Blood-sugar.	Nitro-prusside test.

2. *Potatoes withdrawn from full diet.*—Sugar absent from urine the first day, reappearing to the extent of 2 per cent. on subsequent days. Acetone as before.

3. *Starvation.*—Sugar absent within 24 hours, marked nitro-prusside reaction first day with positive Gerhardt test, intense colour reactions on the second day, after which the patient was restored to full diet.

4. *Glucose-tolerance tests.*

—	Blood-sugar.	Urine.	
		Sugar.	(1) Acetone diacetic. (2) β-Hydroxybutyric.
(*a*) (6/2/25)		per cent.	mg. per cent.
Before glucose . . .	0·085	0·65	(1) 10·0 (2) 20·0
After glucose	—	1·80	(1) 7·3
½ hour	0·121	—	—
1 ,, ...	0·120	—	—
2 hours	0·097	—	—
3 ,, ...	0·075	—	—
(*b*) (12/2/25)			
Before glucose . . .	0·090	2·0	(1) 4·0
After glucose	—	3·2	(1) 2·0
2 hours	0·103	—	—
3 ,, ...	0·080	—	—

Urines collected for four-hour periods both before and after glucose.

5. *Other findings.*—Blood-urea, 32 mg. per 100 c.cm.; cholesterol, 0·250 per cent.; urea concentration (1) 3·1 per cent., (2) 3·0 per cent. Acetone plus aceto-acetic acid and hydroxybutyric acid were estimated by the method of Wrigglesworth (1924),[1] and are much in excess of the most recent average normal values, which are given by Hubbard and Noback (1925)[2] as 0·9 mg. per 100 c.cm. and 0·10 mg. respectively.

Discussion.

The most striking feature, then, is the continuous excretion of acetone bodies, a fact not merely based on a positive reaction but confirmed by more conclusive tests. Its relation to the sugar excretion, itself rather greater and at the same time more variable than in the typical renal glycosuria, is difficult to follow. The mere loss of about 20 g. of sugar per day would normally hardly result in the appearance of acetone, especially where it could be shown that the withdrawal of carbohydrate in the form of potatoes from the diet, or on the other hand, the addition of glucose, had no appreciable effect.

The appearance of a ketonuria in these circumstances is evidently contrary to the present-day theories as to the relationship between carbohydrate and fat metabolism, unless it be assumed that in addition to a very low threshold for sugar the patient had also a lowered threshold for acetone. Unfortunately it was not found possible to carry the investigation further in order to establish whether this were so or not, but since the abnormality cannot be accounted for on the basis of lack of carbohydrate utilisation, it seems feasible to suggest that its cause is a parallel one to that responsible for the abnormality of the accompanying sugar excretion.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BATH.

SECTION OF LARYNGOLOGY, OTOLOGY AND RHINOLOGY.

THIS Section met on three days, under the presidency of Mr. Arthur H. Cheatle.

WEDNESDAY, JULY 22ND.

OVERLOOKED CASES OF FOREIGN BODY IN THE AIR AND FOOD PASSAGES.

A discussion on this subject was opened by Prof. Chevalier Jackson (Philadelphia). He said that his presentation of the subject was from the individual viewpoint of one who metaphorically as well as actually saw narrowly through a small tube; for the broader viewpoint the audience was referred to the internist. Of the 1485 cases of foreign bodies that had come to Prof. Jackson's bronchoscopic clinic in the past 20 years there were over 200 in which foreign bodies had been overlooked for periods of from one month to 30 years. A broad consideration of the histories of these cases showed the outstanding fact that the failure to recognise the presence of a foreign body was due not so frequently to inability to make the diagnosis, as to failure to attach sufficient importance to the consideration of foreign body as a diagnostic possibility. Foreign bodies had been regarded as curiosities of medicine rather than routine possibilities for exclusion. A careful analysis of all the cases in which records were accurate, however, showed that the chief factors in the overlooking of the foreign bodies (not in the ætiology of the accidents themselves) were as follows: (1) Failure to consider foreign body as a diagnostic possibility. (2) Absence of a history of foreign body as proven by over 100 cases at the clinic. (3) Scepticism as to the possibility of the presence of a foreign body, in some instances even in the face of a very positive circumstantial history of the accident. (4) The apathetic attitude of the practitioner. (5) The symptomless interval which usually elapsed after the swallowing of a foreign body. (6) Multiplicity of foreign bodies, one being removed, but others being left behind, this could be avoided by X ray examination after as well as before operation. (7) Waiting for spontaneous expulsion of the foreign body. (8) Simulation, in foreign body cases, of the signs and symptoms of common diseases, such as tuberculosis, asthma, bronchitis, pneumonia, empyema, bronchiectasis; foreign body in the lung would continue to be overlooked until the practitioner deemed it necessary to exclude foreign body in every case of acute or chronic pulmonary disease. (9) Lack of emphasis, in medical teaching, on the exclusion of foreign body in every case of acute or chronic disease of the chest. (10) Groundless assumption of passage by the bowel. (11) Character of the foreign body; vegetable seeds, for example, which did not cast a shadow on X ray examination, might be overlooked. Occasionally, even after a diagnostic bronchoscopy, there might be uncertainty as to the possibility of a small fragment of non-opaque foreign body in a minute bronchial branch; such cases required watching, for sooner or later signs would develop. Every case in which there was the slightest intimation of a foreign body accident, or of the patient having had an attack of choking, gagging, strangling, or coughing, should be regarded as a prima facie case of foreign body. A foreign body, he said, should be regarded as present until the contrary was proven by every means at command. The justification for that rather strong statement was that among his cases there were dozens of histories in which a child after having choked and gagged with food or some foreign substance in his mouth was taken to a practitioner or to a dispensary, or to an out-patient clinic, when entirely symptomless. Physical examination being negative, the parents were reassured and the child sent away. The symptomless interval, often of prolonged duration, prevented connexion of the initial symptoms with the tardy development of the symptoms of foreign body. The Röntgen ray was the most valuable diagnostic means in suspected foreign body; but careful notation of physical signs by an expert should be made in all cases. Expert X ray work would show all metallic foreign bodies and many of less density, such as teeth, bones, shells, buttons, and so forth. If the X ray was negative for foreign body but indicated bronchial obstruction, a diagnostic bronchoscopy should be done. Peanut kernels and watermelon seeds in bronchi produced obstructive emphysema of the invaded side, which should be distinguished from compensatory emphysema, in which the ballooning was in the unobstructed lung.

The relative rarity of foreign body in the air and food passages should not render it an unreasonable rule to exclude foreign body in every ailing child, for was it not a rule for all internists and pædiatricians to exclude Banti's disease as a matter of routine—yet what single clinician or clinic ever saw 1400 cases of Banti's disease? As regards the treatment of overlooked foreign bodies in the lungs, it might be said that 98 per cent. of the localisable foreign bodies of appreciable size that had reached the trachea, bronchi, or parenchyma of the lung through the mouth could be removed by peroral bronchoscopy, and no procedure other than peroral bronchoscopy was entitled to a moment's consideration in the ordinary case of foreign body in the lung. One of the most remarkable things was the recuperative power of the lung from a seemingly very serious pathological condition by a foreign body after the intruder had been removed.

After his opening address Prof. Jackson gave a demonstration on the manikin of mechanical problems of the bronchoscopic and œsophagoscopic extraction of foreign bodies from the air and food passages. After this demonstration he exhibited a number of cinematograph films demonstrating bronchoscopic aspiration for suppurative diseases of the lung of other than foreign body origin; it was remarkable to note the absence of discomfort in patients in whom bronchoscopes were passed into the lungs for aspiration, without any anæsthetic, local or general, in the skilled hands of Prof. Jackson's assistant, Dr. Gabriel Tucker.

Prof. Thomas McCrae (Philadelphia) said that the association of physicians with laryngologists was necessary if there was to be any improvement in the handling of the problem of foreign bodies in the lung. The bronchoscopist had the right to ask the general practitioner and the internal physician that they should be alert and make the diagnosis promptly; they, on their side, had the right to ask that certain laryngologists at least should acquire such skill in bronchoscopy that they could have patients referred to them in the assurance that they would be skilfully handled, and that if necessary a bronchoscopy for diagnosis could be done with perfect safety. He placed emphasis on the importance of the failure to consider the possibility of a foreign body in the air passages; to lessen that mistake a steady process of education was essential, and so long as a foreign body in a bronchus was regarded as something like a fairy tale little progress could be made.

Sir StClair Thomson (London) expressed the thanks of the meeting for Prof. Jackson's brilliant demonstration; he thought that foreign bodies in the air and food passages must be more common in America than in this country, and he blamed the acquisitive habits of the American child.

Sir William Milligan (Manchester) said that he regarded the intimate cooperation with the radiologist as of the utmost value, but where a negative report was given he thought that in any doubtful case an endoscopic examination should be made. He was in favour of a second X ray examination being made after the removal of the foreign body as other foreign bodies might be present. He had known of cases being treated as tuberculosis for years, and clearing up at once on removal of an unsuspected foreign body.

Mr. Herbert Tilley (London) described a typical case of overlooked foreign body, that of a boy who inhaled a paper-fastener into the left bronchus, which illustrated some of the pitfalls which might lead to the overlooking of a foreign body; the chief reason why the case had drifted on was that the chest was not radiographed by an expert directly the trouble occurred. He wondered how many cases of "bronchiectasis," "bronchitis," "pneumonia," and "tuberculosis without tubercle bacilli" had been caused by the presence of an overlooked foreign body, and referred to cases which he had recorded in THE LANCET.[1] If the foreign body was not opaque to X rays the chest should be screened at the moment of full inspiration and again on deep expiration, and a comparison of the two negatives would often show striking differences.

Sir James Dundas-Grant (London) described several cases of overlooked foreign body which had occurred within his own experience. He asked about the use of lipiodol and bismuth in the detection of non-opaque foreign bodies.

Mr. Douglas Crow (Brighton) detailed some of the early difficulties which he had experienced in bronchoscopy; he had found that the practitioner sometimes overlooked the bronchoscopist as well as the foreign body, even when the latter had been demonstrated by X rays.

Mr. G. Ewart Martin (Edinburgh) discussed chiefly the possibilities of the bronchoscope in the diagnosis and treatment of certain affections of the chest; he had obtained very satisfactory results, particularly in the treatment of bronchiectasis by bronchoscopic lavage.

Mr. E. B. Waggett (London) maintained that no examination for suspected foreign body was complete without a skiagram taken in the right antero-lateral position, as in well-developed adults lateral skiagrams of the chest were often obscure.

Mr. Musgrave Woodman (Birmingham) described two cases which came under the category of overlooked foreign bodies in the œsophagus, and showed lantern slides illustrating them.

Dr. P. Watson-Williams (Bristol) referred to the pulmonary symptoms in bronchial occlusion.

In the afternoon, at the Bath Ear, Nose, and Throat Hospital, Mr. V. E. Negus read a paper on evolutionary factors in the causation of pharyngeal diverticula, and also demonstrated a large number of specimens which he had dissected, to illustrate the comparative anatomy of the nose and throat.

Mr. Irwin Moore read a paper on the history of endoscopy, and demonstrated a number of valuable specimens from the special Endoscopic Museum which was the chief feature of the Pathological Museum of the Annual Meeting, and for which he had collected a large number of pathological specimens, endoscopic instruments, &c., from all over the country.

THURSDAY, JULY 23RD.

Chronic Middle-Ear Suppuration.

Mr. G. J. Jenkins (London) opened a discussion on the operative treatment of this condition. He said that operations in cases of chronic suppurative disease of the middle ear were undertaken primarily for the removal of the conditions which were potentially dangerous; secondarily in order to get rid of an offensive state which often necessitated a good deal of care and daily attention; and also, in some instances, with the possibility of improving the hearing. Of recent years many otologists in all parts of the world had been experimenting with methods that were something between the Schwartze operation and the radical mastoid, and which had been termed "conservative mastoid" or "modified radical mastoid" operations. This endeavour to find something better than the radical mastoid operation must have arisen because the latter had been found to be insufficient or defective in some respects. The result was not always satisfactory; sometimes the Eustachian tube remained patent, no matter how carefully that had been provided against. Often the hearing was damaged and sometimes the ear required careful attention for years, even when epithelialisation had been quite satisfactory. Whatever operation was done, the objects should be: (1) to remove all foci of potential danger; (2) to retain the maximum hearing; and (3) to leave a state of affairs that would necessitate the least possible after-attention. Rapidity of healing was a secondary consideration. The cases could be divided into three groups. In the first, the hearing was good, almost as good as in a normal ear, the mechanism of the middle ear not having apparently been damaged; in the second group were included those cases in which the middle ear conducting apparatus had been involved; the third group included those cases in which there was evidence of a gross lesion of the wall of the labyrinth or of the labyrinth itself. In the second group he had tried a modified radical operation of his own devising, the special clinical features which constituted suitability being the presence of a small perforation entirely or almost entirely surrounded by membrane, and evidence that the incus had been damaged; altogether he had operated on 38 cases. The operation might be described as an extended Schwartze operation, with removal of the incus, and the obliteration of the antrum and mastoid cavity by means of a flap of periosteum. The object in removing the incus was, first, to eliminate what he believed to be an important focus of disease which was unlikely to clear up spontaneously; and, second, by its removal he thought that ample drainage would be provided for the antral region until healing had occurred. When, however, there was a serious affection of the tympanic cavity, and especially when the tympanic membrane was extensively destroyed, Mr. Jenkins did not think the results from any form of conservative operation were equal to or as good as those of the radical mastoid operation.

---

[1] THE LANCET, 1908, ii., 1359, and 1911, i., 1066.

Mr. Sydney Scott (London) said that in a case open to doubt as to the necessity for extirpation of the tympanum, when there was no cholesteatoma and no labyrinth disease, even where hearing was very defective, it was permissible to watch the effect of Schwartze's operation as modified by Küster before advising conversion to the epitympanic operation or to the radical operation. For years at St. Bartholomew's Hospital they had recognised the advantages in operating in two stages on conservative principles. Mr. Jenkins had systematised a new stage of conservatism, not a new stage of eradication.

Mr. J. Bowring Horgan (Cork) emphasised that in the overwhelming majority of cases the aural calamity which was designated by the name of chronic suppurative otitis media was a preventable calamity, and that the best treatment of that condition was the thorough and courageous treatment of its progenitor, acute suppurative otitis media. As regards operative treatment, he was convinced of the great value of the primary skin graft in mastoid operations.

Mr. H. Norman Barnett (Bath) said that chronic middle-ear disease was an eminently curable condition, and if under observation and careful treatment it had not been cured in four to six weeks he advised operation and opened up the mastoid antrum. He pleaded earnestly for an early exploration of the mastoid antrum in cases of chronic ear discharge, as it was quite useless ordering drops for such a patient.

Sir James Dundas-Grant said that among the operations for chronic suppurative otitis media the claims of the operation of ossiculectomy had been overlooked. The ossicles seemed sometimes to dam up the discharge, causing violent symptoms which apparently called for a radical mastoid operation; but he had not infrequently found that the symptoms entirely subsided after the removal of the ossicles.

Dr. W. S. Syme (Glasgow) said it was most important to define the actual limits of the disease. The performance of a conservative operation could now be recommended at a much earlier period in well-defined cases in which formerly a radical mastoid operation would have been recommended.

Mr. J. Aldington Gibb (Maidstone) said that recently he had adopted as a conservative measure with good results the transmastoid atticotomy of Bondy, as practised by Sourdille and others in France.

Chronic Non-Suppurative Middle-Ear Deafness.

A discussion on the treatment of chronic non-suppurative middle-ear deafness (excluding otosclerosis) was opened by Sir William Milligan, who said that while otology had made great strides in the past quarter of a century, more especially in the treatment of suppurative disease in and around the middle and internal ears, the treatment of chronic catarrhal and otosclerotic lesions remained practically at a standstill. If it was admitted that in advanced chronic catarrhal otitis media anything approaching a cure was out of the question, our aim should be to endeavour to prevent the onset of the disease and to treat it energetically in the early stages, so as to prevent, if possible, the advent of incurable fibroid changes. In a large percentage of cases the commencement of the disease dated back to childhood or early adult life as the result of some such ailment as measles, scarlet fever, or purulent nasal catarrh. Sepsis was, in many cases, the underlying element in the production of those pathological changes which ultimately led to the connective tissue and arthritic alterations associated with chronic catarrhal otitis media. It was almost unnecessary to recapitulate the importance and the necessity of the removal of septic tonsils and adenoids, and other forms of nasal obstruction and nasal sepsis; but what was necessary to emphasise was the necessity in cases of otitis media of keeping up, for varying periods, a careful toilet of the mucosa. The sheet anchor of treatment was unquestionably inflation by means of the bag or the Eustachian catheter, repeated as often as the particular case demanded. The greater the improvement after inflation and the longer it lasted the better was the prognosis. In order to maintain the patency of the Eustachian tube all obstructive or septic lesions of the throat, nose, and naso-pharynx had to be eliminated. Repeated examination and short courses of treatment were essential if the best results were to be obtained. An important factor in chronic middle-ear deafness was the subconscious loss of acuity of the cortical centres of hearing, and he believed these centres were capable of some amount of re-education, which should be systematised and if possible simplified.

Dr. J. Kerr Love (Glasgow) said that with a sound auditory nerve one should be able to do for a case of middle-ear deafness what the optician did for a refraction error. And yet it did not work out in practice. It was not enough to send the patient to a salesman of "aids to hearing," hoping that the latter would do something The real difficulty was that the acoustician waited upon the aurist, and the latter did not know enough of the pathology of the different types of deafness—the acoustician, of course, knew less. It was possible that because of the mixture of types of deafness the fitting of "auditory spectacles" would never be the success the lens was in the hands of the optician. But, he urged, we should not give up without further trial.

Mr. Neil MacLay (Newcastle-on-Tyne) said that people must be taught to give as much care and consideration to their ears as they gave to their eyes. Of the many remedies for chronic middle-ear deafness the most important were inflation, tympanic massage, and re-educative exercises, the last fairly claiming a certain amount of success. By employing an ordinary conversation tube, amplified if necessary by a receiver of large dimensions, the patient could read aloud to himself or be spoken to at intervals during each day.

Mr. H. Norman Barnett said that his main lines of treatment were the vaporisation of the middle ear through the Eustachian catheter with a mixture of iodine and camphor vapour, and ionisation, which was of very considerable importance in obtaining good results.

Dr. George Cathcart (London) referred to the good results he had obtained in the treatment of chronic middle-ear deafness by re-education of the hearing with the electrophonoide of Zünd-Burguet. He attributed the improvement mainly to stimulation of the organ of Corti and of the cortical auditory centres, in addition to a certain amount of local vaso-dilatation.

Sir James Dundas-Grant was convinced that many cases escaped benefit through the imperfect introduction of the Eustachian catheter. In the intervals of catheterisation the patient could keep up the treatment for himself by the use of a self-inflator containing a few drops of diluted chloroform. Operative treatment was seldom of any value.

Mr. Herbert Tilley said that the early stages of chronic adhesive otitis were frequently overlooked, even by otologists. In the ordinary type of serous exudation into the tympanum, it was his practice to inject through the Eustachian catheter a few drops of 10 per cent. argyrol after having removed the catarrhal fluid by inflation and aspiration with a Siegle's speculum. A few cases improved with endocrine therapy.

Dr. W. S. Syme emphasised the importance of sepsis in the nose and throat; nasal accessory sinus disease was more common than was usually supposed.

Mr. Sydney Scott laid stress on Mr. MacLay's suggestion of employing the speaking-tube in the re-education of the hearing. Dental sepsis had an important relation to deafness, and an X ray examination of the teeth could not be dispensed with.

In the afternoon Mr. Norman Barnett demonstrated at the Bath Ear, Nose, and Throat Hospital a large number of cases of chronic middle-ear suppuration treated by conservative operation, and of chronic non-suppurative middle-ear deafness treated by vaporisation and ionisation.

FRIDAY, JULY 24TH.

Occupational Diseases of the Ear, Nose, and Throat.

A discussion on this subject was opened by Mr. F. H. Westmacott. He said that the subject might most conveniently be discussed under two headings: (1) Industrial diseases which were included in Schedule 3 of the Workmen's Compensation Act of 1906, extended by various orders, and included in the Act of 1923; (2) industrial diseases which were met with in workers but which were not so included and might or might not cause incapacity of employment. In the first category the list of diseases affecting the ear, nose, and throat included anthrax, lead, mercury, phosphorus and arsenic poisoning or their sequelæ, poisoning by nitrous fumes, ulceration of the mucous membrane of the nose or mouth produced by dust, chromic ulceration, compressed-air illness, glanders. Among the second group were inflammation of the auricle followed by slough and necrosis, as occurred in cold-storage workers; rupture of the tympanic membrane due to explosions in mining, blasting, tunnelling, or gun-firing tests; acute or œdematous laryngitis might be directly caused by inhalation of irritant fumes of chlorine, bromine, iodine, ammonia, or sulphuric acid; membranous laryngitis, non-diphtheritic, occurred in workers in steam and irritating vapour, such as in stokers and cooks; chronic laryngitis was found among professional voice users, from misuse or faulty voice production; hypertrophic laryngitis was frequent in street hawkers, salesmen, or those exposed to dusty occupations. In continuous noises, such as riveting in boiler-making or loud machinery, which gave rise to continuous nerve strain, deafness was due not so much to damage to the sound-conducting mechanism as to destruction of the sensitive nerve-endings which constituted the sound-perceiving apparatus. More severe deafness was produced by intense sounds made up largely of overtones of high pitch than by noises of lower pitch such as were heard, e.g., in cotton mills. Tinnitus was invariable, but vertigo was only present in direct proportion to the loss of perception of the upper tone limit.

Surgeon-Commander S. W. Grimwade, R.N., said that with the exception of diseases of the ear, occupational diseases of the ear, nose, and throat were not at all common in the Royal Navy. During nearly two years' service at the R.N. Hospital, Plymouth, he had seen only four cases of labyrinth concussion from gunnery practices; all of these showed a very marked degree of deafness, which, however, was temporary, and they soon returned to normal. 99 per cent. of all cases of deafness in the navy were due to suppuration of the middle ear, and there was no question that more careful examination of recruits would eliminate a large number of these cases.

Wing-Commander D. Ranken, R.A.F.M.S., said that they found in the Royal Air Force that the effects of nasal obstruction, though disagreeable enough on the ground, were intensified in the air; the engorged nasal mucous membrane associated with high altitude frequently gave rise to insufficient ventilation and drainage of the frontal sinuses, and pilots often complained of headaches of varying duration during or immediately after descent. More important still was the presence or absence of Eustachian obstruction, for if equalisation of the pressures on either side of the ear drums by means of swallowing or auto-inflation could not be made during a rapid descent, pain and deafness together might occur, with such effects of labyrinthine disturbance as vertigo, nausea, or even fainting. There were two methods of preventing aeroplane deafness: harmful sound waves were cut off at their source by fitting silencers to the engines, and the persons exposed to noise were protected by ear protectors on the principle of a "baffle" system.

Major T. Jefferson Faulder, R.A.M.C., T.F., said that, showing the magnitude of the problem, the total number of first awards of war pensions for various aural disabilities had been 31,750; in December, 1924, this had diminished to 18,500, and approximately one-half of this total was assessed at 20 per cent. or less disablement. During the war admissions to hospital on account of ear conditions amounted to a total of 182,440, diseases of the nose 37,520, diseases of the respiratory organs other than tuberculosis 801,840, tonsillitis and sore-throat 441,040. As regards the question of ruptured drum-head, various opinions had been given, usually, in his own opinion, in the direction of over-estimation.

Mr. E. B. Waggett considered that the statistics of the recent war gave a wholly misleading impression, and he believed that the very heavy figures concerning hospital entries of chronic otorrhœa, aural, nasal, and throat operations, were to be explained on psychological rather than surgical grounds—chronic otorrhœa formed a convenient excuse for the soldier desiring a holiday at the base.

Dr. T. Ritchie Rodger (Hull) said that the sounds prevailing in boiler-making works were comparatively low in the scale, ranging round about 400 and 500 double vibrations per second. In regard to the occupational deafness of boiler-makers the mass of evidence was that the injury to the cochlea was conveyed by air-conduction, not by bone-conduction; middle-ear defects had no part in the causation. Meatal plugs of wax or vaselined wool were the only aids to prevention of the disability.

Mr. T. B. Jobson (Guildford) said that in 1915 he had had the opportunity of examining 50 German soldiers shortly after their exposure to prolonged gunfire, and about 80 per cent. of them showed diminution of acuity of hearing both for air- and bone-conduction. In from three to six months almost all of the cases had returned to normal.

In the afternoon Dr. P. Watson-Williams gave a demonstration of his method of making a complete investigation of the nasal accessory sinuses.

SECTION OF THERAPEUTICS.

WEDNESDAY, JULY 22ND.

Treatment of Asthma.

This Section met on three days, under the presidency of Prof. R. B. Wild.

Dr. W. Langdon Brown (London), in opening a discussion on this subject, said that the treatment of asthma summarised in itself, as it were, the chief trends of modern therapy: Psychotherapy, sensitiveness to foreign proteins, vagotonia, and endocrine balance. Successful treatment involved them all. Asthma was due to an unstable or irritable condition of the bronchomotor and vasomotor portions of the vagus nucleus, which caused it to react unduly to psychical or peripheral stimuli, or to foreign proteins in the circulating blood. The influence of the parasympathetic nervous system was also extremely important in asthma. The asthmatic, he said, was liable to other manifestations of vagotonia. It might, however, be that the vagotonia was due to a diminished action of the antagonising sympathetic nervous system. The sympathetic nerves activated those endocrine glands which released sugar into the blood, and in asthma the blood-sugar was below normal. The secretions of glands which coöperated with the sympathetic nervous system—the adrenals, pituitary, and thyroid—were generally effective in checking a paroxysm. Further, the liability of asthma to come on during sleep, when the parasympathetic nerves had the upper hand, pointed to a disturbed balance between the two great branches of the visceral nervous system. In general terms it would appear that when the endocrine balance swayed in the direction of the vagus, asthma was likely to occur in susceptible subjects; when the balance was redressed in favour of the sympathetic system attacks might be cut short or prevented.

In considering treatment, the suggestibility of the patient should be utilised to help him to expect a cure. Sources of peripheral irritation must be eliminated, including late suppers and cold bedrooms. Specific desensitisation presented considerable difficulties both because the actual cause could not always be found by skin tests and because hypersensitiveness was not always constant for one subject but might affect a whole group. Non-specific treatment might, however, be successful. The effect of climate was well known to be capricious, but at altitudes above 4500 feet attacks were very rare. Oxygen inhalations might act in the same way as pure or filtered air. Drugs which paralysed the parasympathetic endings or stimulated the sympathetic were also helpful.

Dr. E. P. Poulton (London) said that, defining asthma as a bronchial spasm with vasomotor turgescence, there were several causes of the condition. Asthma due to bronchitis or nasal coryza should be sharply separated from the idiopathic variety or allergia. The cardiac asthma of elderly patients was also a separate entity. The allergic group included other toxic idiopathics besides asthma. Skin reactions were of no value in diagnosing the cause of asthmatic attacks, but Loewe's extract of human dandruff might be of great use in determining whether a patient belonged to the allergic or to some other type. Asthma, in his opinion, was not due to anaphylaxis any more than histamine shock was due to anaphylaxis. Treatment might be directed towards: (1) Desensitising the patient either by specific or non-specific means; (2) keeping him away from the specific exciting substance; (3) acting on the receiving mucous membrane of the nose, as by light cauterisation; (4) altering the condition of the bronchial muscle and removing spasm by subcutaneous adrenalin or caffeine or by oxygen inhalation.

Dr. P. Hamill (London) said that it was wise to take a careful history and to consult the patient as to the cause of the attack. It was generally possible in this way to get at the exciting factor. He agreed with the previous speaker that it was difficult to achieve specific immunity, but non-specific immunisation might be tried. Peptones could be given by mouth for the purpose. Cases with a *M. catarrhalis* infection benefited by autogenous vaccines; but it was necessary to start with a very small dose as the patient was highly sensitive. Many drugs could be employed. The vagus endings could be paralysed by atropine or hyoscine, the sympathetic stimulated by adrenalin and cocaine; the bronchial muscle could be relaxed by nitrites, papaverine, or benzyl benzoate. Pituitrin and adrenalin were very effective in cutting short an attack if given at the beginning. Oxygen was useful if given efficiently, and some of the patients suffered from chronic oxygen lack. It was necessary to improve the general health and resistance and treat the patient as well as the disease. Arsenic, bromides, iodides, and thyroid were all useful.

Dr. Alexander Francis (London) said that the indiscriminate use of cautery to the nose did much damage. He gently touched certain spots on the mucosa keeping a careful watch on the blood pressure meantime. This was effective in 80 per cent. of cases, excluding those with nasal polyp. Cases complicated by nasal polyps were invariably made worse if cauterised or if the polyps were removed.

Dr. A. F. Hurst (London) said that, speaking as a sufferer for 30 years from asthma, he believed there was no cure for the condition, the patient always remaining a potential asthmatic. To ward off attacks adrenalin was invaluable if properly used. It must be given at the very beginning of an attack, when 1 minim would suffice. More than 3 minims was never required at this stage. He recommended that the patient should have an injection ready by his bedside so that he could give himself the drug the moment he felt the premonitory symptoms. The injection could be repeated as often as was necessary. If these instructions were carried out the patient need never lose a night's rest, and the fatigue which rendered him liable to further bouts was avoided. In fact, the best cure for asthma was not to have attacks.

Mr. Frank Coke (London), in spite of the dicta of previous speakers, believed in the efficacy of protein tests. He classified the types of asthma. Every single case must be fully and properly tested with every protein with which the patient comes in contact. The offending proteins must be avoided. If this is impossible, as in the case of horse dander, pollen, and proteins causing occupational asthma, the patient must be desensitised.

Dr. S. D. Bhabha (London) described an apparatus for administering oxygen which had been found successful in the treatment of asthma, and the President of the Section drew attention to the relation between asthma and eczema. The two conditions sometimes alternated in the same patient.

Dr. Langdon Brown, in replying to the discussion, agreed with Dr. Poulton's use of the term allergy. He thought that the value of skin tests was general rather than specific, and that they succeeded best when the cause of the asthma was already known. In reply to Dr. Hamill, he said that in his experience the action of amyl nitrite was somewhat uncertain. He had sometimes had great success with papaverine. He agreed with Dr. Francis as to the beneficial results of light cauterisation. With regard to the President's remark on the connexion between eczema or asthma, he showed the pedigree of a family in which the two diseases had appeared alternately in the different generations.

THURSDAY, JULY 23RD.

Treatment of Chronic Arthritis.

In opening a discussion on this subject, Sir Thomas Horder (London) laid stress on the usefulness of weighing the ætiological factors in each case. Although these were frequently obscure, there was good reason for thinking that a microbic factor was invariably present. A table to show the relative importance of this factor might be constructed as follows:—

INFECTIVE FACTOR	*Joint Disease.*
HIGH. ↑	Gonorrhœal rheumatism. Chronic pyæmia. Arthritis due to streptococcal, pneumococcal, dysenteric, and coliform infections. Tuberculous and syphilitic arthritis.
	Arthritis in association with focal sepsis. "Rheumatoid" arthritis. Osteo-arthritis.
	Gout.
↓ INFECTIVE FACTOR *Low.*	Arthritis in tabes, syringo-myelia, hemiplegia, and paralysis agitans.
	Trauma.

Arthritis as a definite expression of *focal sepsis* formed an intermediate group between the cases of direct joint infection and those termed "rheumatoid," which, owing to our present ignorance of the degree to which the element of infection was present, formed the crux of the therapeutic problem. In this intermediate group drainage or other appropriate treatment of the area of focal infection was the first step in treatment. More than one area was sometimes involved, in which case it was important to determine as far as possible which was primary—and attend to that first. Where teeth and tonsils, or teeth and gastro-intestinal tract, were both involved the teeth should receive attention first. The speaker discussed the rôle of the prostate, the uterus, and the alimentary tract in arthritis. Streptococci, both hæmolytic and non-hæmolytic, were probably by far the most common organisms concerned. Antigen therapy must be supplementary to drainage of the infected area and not a substitute for it. A diet which lowered the bacterial content and caused mechanical cleansing was probably more important than the use of intestinal antiseptics; but amongst these calomel and salol must not be forgotten.

In the great majority of cases, the speaker said, chronic arthritis was part of a general disease, for which the patient required treatment. The nutritional and the nervous aspects must both be carefully considered. Endocrine disturbance was frequently present, and small doses of thyroid were often helpful. The possibility of a metabolic factor, such as gout, must not be forgotten even in cases of marked infection. Protein-shock therapy gave relief in suitable cases, but the final results were not always favourable. It was definitely contra-indicated in active disease, or where there were visceral or serous membrane complications, such as pleurisy, "stagnant" cases should be chosen; and there was grave danger in teaching students to use methods which may easily be misapplied. It was sometimes said that the infectivity of most cases of chronic arthritis made the idea of spa treatment irrational; but if arthritis was a general as well as a local disease this reasoning was fallacious. There was undoubtedly as great a field for the treatment of these cases by spa measures as ever, and of radium waters and radio-active mud we were only now beginning to learn the potentialities. Sir Thomas Horder then went on to describe the local measures available. All efforts to restore and improve the function of diseased joints reacted beneficially on the general condition, and local treatment must prepare the limbs for an arrest of the disease which might occur at any moment.

Dr. Preston King (Bath) spoke on the balneological aspect of treatment of chronic arthritis. He thought that the value of spa treatment was generally acknow- ledged, and that the value of the Bath Spa was a very high one owing to the thermal character of its waters which rise at a temperature of 117° F. There were, of course, many factors producing beneficial reactions in patients, and the sceptical emphasised the factor of suggestion. Suggestion did play a part, but it was nothing new: it was as old as the practice of medicine itself. He referred to the different types of arthritic disease and their reaction to balneological treatment. In his experience the asthenic case of rheumatoid arthritis with rapid pulse, emaciation, sweating, and peri-articular swellings did not respond well to full bath treatments. Such cases were apt to do badly anywhere under any treatment, but tonic treatment with douching was the most suitable. Chronic arthritis in all forms was amenable to hydrotherapy. Treatment was directed to: (1) the relief of pain; (2) the removal of sources of infection; and (3) increasing the mobility and correcting the deformity of the joints.

Dr. Nathan Mutch (London) agreed with the remarks of the opener on the importance of the drainage of any area of focal sepsis which could be discovered; but the removal of foci of infection often proved a failure as regards improvement of the patient's condition. This might be because, although the original focus had been cleared out, the infection had already spread far beyond reach and escaped detection. A frequent source of infection was oral sepsis, and years after this had been eradicated, pathogenic streptococci of oral orgin might be recovered from the stools. If the bacteriological content of the bowel at different levels was studied at laparotomy, it was often found that the ileo-cæcal region was especially heavily infected, and an infection might be found above this level in the jejunum or even in the duodenum. Positive cultures might also be obtained in the lymph glands draining the bowel, indicating a widespread infection passing to the blood-stream and the lymphatics. It was not, he thought, generally realised what an enormous daily variation occurred in the bacterial content of the stools. The number of streptococci present might vary from nil up to ten times that of the *B. coli* present in different specimens, or even in different parts of the same specimen. Five to six specimens at least should be examined before giving an opinion in a difficult case. This variation should be taken into account in judging the results of drug treatments, and would also help to explain the want of uniformity in laboratory reports complained of by the opener. With regard to vaccine treatment, it was advisable before beginning this to consider the degree of toxæmia present. The reaction to vaccines varied with the activity of the toxic conditions, and this should, if possible, be reduced first. Lesions of joints and affections of the endocrine glands were often coincident. The thyroid more especially was frequently affected, and the giving of thyroid extract might assist other lines of treatment. Secondary infections and invasions often occurred. One organism might be followed by another. Joint reactions might be obtained by the injection of intestinal streptococci, when the original infection was known to have been a staphylococcus or a virulent streptococcus from the mouth. Organisms were not *the* cause of arthritis. Probably there was no one cause, and multiple causes should be looked for in all cases.

Dr. C. B. Heald (London) contributed to the discussion from the point of view of the cases as treated in an electrical department. He considered that they might be classified from their reaction to treatment as: (1) The stationary group, composed of those who are relieved of their symptoms so long as they continue under treatment and relapsing as soon as treatment is stopped; (2) the progressively improving group, which responds satisfactorily; and (3) the group that shows no reaction and is unrelieved or gets steadily worse. He found that cases were curiously selective in their reaction to electrical treatment; and as regards the form of treatment to which they responded, he was unable to distinguish clinically into which of the three groups a case would eventually fall. He thought that the reaction to treatment might vary with the basic variation of physical type. When studying variations of defective physical types in men presenting themselves for pilots in the Air Force, he had found that they might in general be placed in three classes: cardio-vascular debility, nervous debility, malnutri- tional debility. Before commencing treatment it was exceedingly important to take a careful history and to make a complete routine examination. Among other methods he always examined for areas of hyperalgesia by means of a small faradic current. The presence of positive zones was not diagnostic, but if they were present the patient was likely to show a bad reaction to treatment. Treatment was directed towards improving the basic condition and the local condition. For the nervous debility type of patient he used ultra-violet light with selected local treatments. For the cardio-vascular debility type he used diathermy, especially applied to the abdomen.

Mr. E. Watson-Williams (Bristol) thought that the importance of infections of the upper air passages should be realised and the sinuses carefully examined in every case. Although the gastro-intestinal tract might seem to be the primary source of an infection, this originated in many cases in the upper air tracts and the organisms had passed downwards through the stomach at some period when the hydrochloric acid was diminished. Therefore sinus infections should be eliminated first in all cases. Neurasthenic conditions, too, might be kept up by the presence of chronic infections, and even crippled patients might be improved by the discovery and removal of a sinus infection.

Dr. E. P. Cumberbatch (London) stated that he was a believer in the value of electrical methods of treatment, and especially in the use of diathermy in the treatment of gonococcal arthritis. If there were no gross changes the use of diathermy would cure, and in any case it would give improvement. The treatment was applied to the seminal vesicles or to the cervix uteri, and needed to be very carefully directed both as to dosage and details of administration. In non-gonococcal cases in women there was frequently an infection of the cervix, with endocervicitis and erosion. The organisms obtained in such cases might be coliform organisms, diphtheroid organisms, or a *Streptococcus fæcalis*. These, too, he treated with diathermy, with the result that in many cases the arthritis was arrested, there was an improvement in the general health, and the cervix was restored to a normal appearance. He raised the cervix to a temperature of 114° F., but not exceeding 115°. He standardised the temperature by application to the urethra, which was sensitive to heat, whereas the cervix was not.

Dr. David Campbell thought that rheumatoid arthritis presented two problems—the orthopædic problem and that of the cure of the infective process. He thought that there was great danger in immobilising the joint. In cases of the infective type of rheumatoid arthritis protein-shock therapy was worth trying. He had not observed any case of pleurisy following the use of typhoid vaccine, which was the one he had used; but he had seen two patients who, having had albuminuria previous to the injection, had developed a transient hæmaturia.

The President remarked upon the curious fact that the onset of damp weather should cause changes of a sensitive nature in joints which are themselves continually bathed in fluid. It appeared that when the humidity reached a certain point the elimination of carbonic acid from the body was much diminished, and it was possible that one might find in the accumulation of carbonic acid an explanation of these obscure pains.

Dr. P. Hamill thought that whilst harm could be done by too rigid splinting, one of the first principles of treatment of acute inflammation was rest, and therefore he remained unrepentant concerning his use of splints in moderation, though exercise and massage should certainly be employed in addition.

Dr. Warren Crowe (Harrogate) said that in arthritis and non-articular rheumatism (for the two conditions could be classed together) vaccines ought to do well. Every active case of chronic arthritis under vaccine treatment, almost without exception, passed through a stage of sensitiveness to vaccine, and this was sometimes so intense that vaccines were for a time not tolerated at all. When the clinician recognised this fundamental fact his results would be very much better.

Dr. F. G. Thomson (Bath) said that much depended on the general condition of the patient. If the general condition was poor the best course was to send the patient to a spa. If the general condition was good the most valuable thing for practical purposes was to use intravenous shock.

Sir Thomas Horder, in replying, said that he had not intended by any means to impugn the value of the work of the bacteriologist. He could not get along without him, but he thought it desirable to ginger him up occasionally. He wanted to make it plain that he did not advise protein shock in the case of a patient who was improving by any other method. To come back to his main thesis, which he thought the discussion had strengthened, he held that arthritis was a general disease with local manifestations, and for that reason the patient must be studied quite as much as the joints.

FRIDAY, JULY 24TH.

Therapeutic Value of Light.

At this meeting of the Section, Prof. W. E. Dixon (Cambridge) in opening the discussion, said that the subject was the therapeutic value of light. It had nothing to do with X rays or radium. The actions of light which could be easily demonstrated on animals or man were of three varieties: local, general, and specific. The local and general reactions might be produced by certain other irritants. The specific action was possessed, as far as was known, only by light. The local effect consisted of erythema, which might be followed by swelling of the skin, blisters, or even breaking down of the skin. Mustard had a similar action. The mechanism was an irritation of sensory nerves which, by means of an axon-reflex, produced dilatation of the blood-vessels in the skin or subcutaneous tissues. The proof of this was that if the nerve was cut or anæsthetised the reaction no longer occurred. For instance, if a drop of mustard solution was put into the eye of an animal, the result was acute inflammation of the conjunctiva, but if the eye had been previously anæsthetised with cocaine, inflammation did not occur. Although the mechanism could be explained, the problem was not quite so simple as it appeared. How was it that both mustard and light could stimulate nerve-endings? The stimulation was brought about in different ways. Mustard underwent hydrolysis in contact with the skin. Energy was thus liberated for the stimulation of the nerve-endings. It was not known how light excited nerve-endings without affecting other tissues, but it was probably due to the presence of fluorescent substances in the skin. If these substances were exposed to light their action was greatly enhanced. One such fluorescent substance was hæmatoporphyrin, obtained during the breakdown of hæmoglobin to bilirubin. People with excess of hæmatoporphyrin were sensitive to light. This could be proved experimentally by injecting mice with hæmatoporphyrin. When the mice were exposed to light the skin became red and swollen and the animals might die. Summer prurigo and hydroa vacciniforme were a result of excess of hæmatoporphyrin in the skin in man.

Pigmentation was another non-specific local effect. It was a protective mechanism the object of which was to absorb ultra-violet light. The general effects of light were a mild stimulation of medullary centres, slight increase of the pulse-rate, with vaso-constriction and rise in blood pressure, and stimulation of respiration. There was an increased activity of the tissues, as shown by the increased power of phagocytosis of the leucocytes. The specific effect of light was its influence on the storage of calcium and phosphate in the body. The ingestion of calcium by the mouth did not alter the percentage of the salt in the tissues any more than drinking water diluted the blood. Children could be prevented from getting rickets or cured of the disease by light. The point to discover was whether light acted on the surrounding air, on the food, or on the body. It had no effect on the air, but its effect on foodstuffs and on the body was important. Wheat, biscuits, flour, milk, eggs, lard, linseed oil, cotton-seed oil, and other substances which of themselves were incapable of influencing rickets, when irradiated assumed antirachitic properties. All these foods contained cholesterol. Cholesterol underwent changes on exposure to light. It became yellower and more translucent. This altered cholesterol had the property of preventing rickets. The skin contained a large amount of cholesterol and therefore exposure to light had the same effect as feeding with irradiated cholesterol-containing foods. Experiments on rats showed that feeding with skin had no effect in curing rickets, but the animals were cured when they were given skin which had been exposed to light. Too long exposure to light was harmful. In Sweden it had been found that certain groups of people, notably neurotic patients, were made worse by light treatment. If the observations made on cholesterol held good, there should be parallelism between the incidence of rickets and the amount of available sunshine. There were no good statistics on this point, but the information he had did not show any such relation. In the Panama zone there was little sunshine but no rickets. In the State of New York there was more sunshine but rickets was prevalent.

Dr. C. E. M. Jones (Alton) said that clinical phenomena could not always be explained scientifically. The two diseases in which light treatment had been found most effective were rickets and tuberculosis. From the clinical point of view the general action of light was more important than the local. Heliotherapy or natural sunlight aimed at producing a feeling of exhilaration and increased well-being in the patient. Certain patients could not be exposed to light and were known as non-pigmenters. They were, as a rule, fair or sandy haired, freckled people who got burnt instead of becoming pigmented. Pigmenters had a higher resistance to non-pulmonary tuberculosis than non-pigmenters. The feeling of exhilaration after heliotherapy was accompanied by increased metabolic activity. The latter might be attributed to exposure to the air and apparently did not occur with artificial light treatment, which was carried out in a room. We were familiar with psychological action of light in increasing cheerfulness. Increase of mental activity had been observed in children treated by light. Exposure to light must be graduated, otherwise depression and collapse supervened as happened with non-pigmenters. If a child who was a non-pigmenter had bone or joint tuberculosis and the lesion became quiescent it would almost certainly relapse or the child would get a fresh lesion. If the fresh lesion was treated often pigmentation supervened, and then the disease might be cured. If the patient did not have some power of acquiring pigmentation he appeared unable to shake off the infection. The effect of air and light on muscular wasting was remarkable. In cases such as those of tuberculosis of the hip, which in hospital always presented wasting of the muscle, there was practically none with treatment by heliotherapy, although the limb was immobilised in the same way. Artificial light was useful when sunlight was not available. Here the local action was much more important, but the best effects were obtained when local was combined with general light baths. He had obtained good results in the treatment of lupus. Light treatment was contra-indicated in non-pigmenters, febrile cases, in those who were acutely ill, in amyloid disease, and in the very young or the very old.

Dr. G. H. Lancashire (Manchester) said that great advances had been made in recent years in the treatment of skin diseases. He was one of the first people in this country to use Finsen's lamp, and had obtained very good results with it in lupus. Recently at Manchester they had installed a modern artificial light apparatus which was reserved for tuberculous cases. The results, especially in lupus, had been more successful than he had dared anticipate. The patients were given a general exposure to the light with the lesion covered. The cosmetic results were very good. Healing had been obtained in cases of buccal and nasal lupus. He had seen remarkable benefit from light treatment in alopecia, but he would like to utter a warning against making too wide a claim for the method. Light therapy should be reserved for cases where it gave better results than other forms of treatment. Evidence as to its special efficacy should be published before it was recommended in any particular skin disease.

Dr. William Mitchell (Bradford) spoke of his work at the Bradford Royal Infirmary, where he had treated cases since 1906. The chief conditions for which he employed light therapy were lupus, alopecia areata, tinea, acne, and lupus erythematosus. In lupus vulgaris a preliminary dose of X rays was of advantage. Cases of tuberculosis of the spine and glands did well provided that no abscesses had formed. Their presence was a contra-indication to the treatment. In lupus erythematosus better results were generally obtained with carbon dioxide snow and ether; but in some cases light was useful. For acne he preferred filtered X rays.

Dr. P. Heffernan (Buxton) asked whether any work had been done on the influence of light on iodine metabolism. Dwellers in dark and narrow valleys were liable to develop goitre due to iodine starvation. He would like to know whether sunlight had any power of fixing iodine in plants or of enabling the body tissues to make use of iodine.

Dr. J. R. Garrood (Huntingdon) suggested that the factor responsible for pigmentation or non-pigmentation might be racial. Mediterranean blood was widely prevalent in this country, and the Mediterranean type survived exposure to tuberculous infection better than the Nordic.

Dr. E. P. Cumberbatch asked to what depth the arterioles were affected as the result of an axon-reflex from stimulation of cutaneous nerves. He would also like to know whether it made any difference to the clinical results whether the patient was exposed for three minutes to a mercury lamp or for half an hour to a carbon lamp.

Dr. Newman Neild (Bristol) said that patients were apt to take the cure into their own hands with disastrous results. He had two cases of phthisis who had exposed their chest to the sun without medical advice and a bout of pyrexia had followed.

Dr. Helen Mackay (London) said that her experience had differed somewhat from that of other speakers. Neurotic children suffering from irritability did well under light treatment. They became much happier. In babies if the dose was increased too rapidly the child remained happy but stayed awake. If the dose was cut down the child immediately slept well. Moderate stimulation was good, but an overdose caused undue excitability and must be avoided. Cases of eczema benefited when light was added to local treatment. She had had good results with wasting babies, but it was extremely difficult to foretell which children were going to do well with light.

Dr. J. M. H. Munro (Bath) called attention to the analogies between tuberculosis and rheumatoid arthritis. In both treatment aimed at raising the metabolism generally. To this he attributed the good results obtained in arthritis with light therapy.

Dr. T. B. Poole (Westcliff) spoke of the benefits of calcium administration in menorrhagia and chilblains, and concluded that the drug was absorbed into the circulation.

Dr. Jones, in reply to Dr. Cumberbatch, said that he had found no difference between the two methods of exposure from the clinical standpoint; but he himself preferred the carbon lamp because it more closely resembled sunlight. He did not agree with Dr. Mitchell that abscess formation contra-indicated light treatment. He had had success in a case of tuberculous spine with abscesses. As Dr. Neild had said, there was a good deal of risk in pulmonary tuberculosis from unsuitable exposure.

Reply.

Prof. Dixon, in replying to the discussion, said that clinical observations could not always be explained by science. Science was only the handmaid of medicine. He agreed that pigmentation varied with the patient's resistance. Dr. Jones's observations and Dr. Garrood's explanation were both in agreement with Charles Darwin's statement that only the people who became black were able to resist certain tropical diseases and therefore they had survived. He did not know of any work on the influence of light on iodine metabolism. The question of calcium absorption had nothing to do with this discussion on light; he would only say that, unless there was calcium starvation, taking calcium by the mouth did not increase the amount in the blood, nor did it increase the clotting power of the blood. In reply to Dr. Cumberbatch, he said that the reflex from cutaneous nerves acted on the vessels in the subcutaneous tissues down to the muscles. Dr. Mackay had spoken of overdoses of light. Stimulation was always followed by depression. Unfortunately, we had at present no means of gauging the amount of light administered.

Dr. Newman Neild read a paper on the

Uses of Posture for Bronchial Drainage.

In order to drain the bronchi, he said, the patient must be placed in such position that the bifurcation of the trachea was lower than both bronchi. There were three practicable positions in which this result might be obtained—namely, on the back, on the face, and on the side. The best and the one most comfortable to the patient was on the side but turned a little towards either the face-down or the on-the-back positions. The patient would lie on his right side, with the head low and the waist raised with pillows, so that the highest point was under the lowest ribs. The right ear would be close to the edge of the bed so that the mouth would be over the side. The position must be maintained by suitably placed pillows. This posture was excellent when prolonged drainage was required. If only one side of the chest required drainage that side should be uppermost. Cases treated successfully by the adoption of this posture included hæmoptysis, pharyngeal paralysis, bulbar palsy, cerebral disease, and various conditions complicated by bronchitis. If dying patients were placed in this position the death rattle, which is so trying to others who are in the same ward, would cease.

Reviews and Notices of Books.

THE MECHANISM AND GRAPHIC REGISTRATION OF THE HEART-BEAT.

Third edition. By Sir THOMAS LEWIS, M.D., F.R.S., &c. London: Shaw and Sons. 1925. Pp. 529. 50s.

SINCE the appearance of the last edition of this monograph the results of some important researches in cardiac physiology and therapeutics have been published in this and other countries. A mass of new evidence has been collected—a very considerable part of it in Sir Thomas Lewis's own laboratory at University College, London—and a step forward has been made in our knowledge of certain aspects of the subject. This recent work is ably summarised in the present volume. Each new hypothesis considered is submitted to the same careful and well-balanced criticism which characterised the previous edition, and when, in the author's opinion, the evidence at present available is insufficient to justify a definite conclusion, the observed facts are clearly stated, and the reader is left to form his own judgment.

One of the objects of science is to simplify knowledge by developing general hypotheses which will correlate and explain what had previously been an apparently disconnected mass of observations. In the new chapters of the present book which deal with circus movement and with the membrane theory of electrical phenomena, the reader can catch a glimpse of two mechanisms which have already shown promise of bringing together observations hitherto more or less isolated and obscure. The researches of Mines and Garrey originally suggested circus movement as the cause of fibrillation; but at the time that the second edition of "The Mechanism" went to press an alternative hypothesis received the support of the author. In the present edition five chapters are devoted to the consideration of circus movement, the refractory period, and closely allied problems; while two others deal with the possible rôle played by circus movement in the genesis of extrasystoles and paroxysmal tachycardia, and with the alternative hypothesis of parasystole. Another new chapter treats of the nature of heart-block. In addition to these major alterations and additions, much of the text has been rewritten to conform with the most recent advances in our knowledge, and many new figures have been introduced. To deal in detail with these various points is beyond the scope of a review, and it must suffice merely to enumerate as examples the sections dealing with "the law of cardiac muscle," the relation of excitation to contraction, the membrane theory of electrical changes in muscle, and the significance of aberrant ventricular complexes.

There is one aspect of the subject which might with advantage be treated more fully in a future edition—namely, the instrumental investigation and the graphic registration of heart sounds and murmurs. The various devices employed by Einthoven and his colleagues, by H. B. Williams and by Wiggers, each have certain advantages over the older method with the carbon microphone. Year by year as specialisation increases it becomes more and more difficult for the clinician to keep in touch with the growing point of knowledge. The general physician of to-day must be content to receive most of his mental nourishment in a predigested form, but for those who still prefer to masticate their own food, and are prepared to curtail the number of courses on the menu, a book such as this is invaluable. It summarises recent work, it affords an easily accessible and very complete bibliography, and last, but not least, it gives the reader the benefit of the carefully considered opinion of an expert critic.

Sir Thomas Lewis's book holds a unique position in the literature of modern cardiology.

MANUAL OF PRACTICAL X RAY WORK.

Third edition. By JOHN MUIR, B.Sc., M.B., Ch.B., Assistant Radiologist, University College Hospital. London: William Heinemann. Pp. 524. 31s. 6d.

THIS excellent manual was first published in 1908 under the joint authorship of Dr. J. Muir and Dr. D. G. Arthur. In this third edition Dr. Muir has done the re-writing and revising in collaboration with the late Sir Archibald Reid and Mr. F. J. Harlow, of Blackburn, and no doubt the help and advice received has greatly enhanced the value of the book. The gastro-intestinal section, although not unsatisfactory, seems to be its least adequate part, and here some amplification would be useful. New methods and observations on such subjects as orthodiagraphy, pyelography, gall-stones, and eventration of the diaphragm are dealt with clearly and in sufficient detail for a text-book, while a small appendix on the radiography of the pregnant uterus is added.

Of good X ray books there are few, but this one can be recommended to the practitioner with confidence, and particularly to students who are studying for a diploma in radiology. Finally, the illustrations are sufficiently numerous, good, and clear. We have one criticism. Nearly all the modern X ray text-books are devoting more and more space to technical descriptions of X ray tubes, electrical supplies and apparatus. This seems often to be a great waste of time, space, and energy on the part of the authors. In this volume, for instance, 100 pages are given up to this technical electrical description out of a total of 524 pages, and practically all the information can be got from the excellent descriptive catalogues which are nowadays published by instrument makers. It seems that the space might be more usefully employed by a medical writer.

PATHOLOGY.

Text-book of Surgical Pathology. By C. JENNINGS MARSHALL, M.D., F.R.C.S., Assistant Surgeon to Charing Cross Hospital; and ALFRED PINEY, M.D., M.R.C.P., Director of the Institute of Pathology, Charing Cross Hospital. London: Edward Arnold and Co. 1925. Pp. 460. 21s.

ONLY occasionally does it fall to the lot of the reviewer to deal with a book for the production of which it can be truthfully said there was real need. The appearance of this volume provides one of these rare occasions. While it cannot be said that the comprehension of the pathological basis of surgery advances at such a rate as to render the older text-books on the subject obsolete, none the less changes in thought occur and the manner of looking at things alters on small points sufficient in the mass to make a text-book, unless frequently re-edited, date very perceptibly. And of the older standard text-books of surgical pathology there have been no new editions for several years.

The present volume is all that a text-book should be. The style is clear and concise; the illustrations, with the exception of some of the reproductions of X rays and the microphotographs, are excellent; the latter are as good as pictures of their class can be, but in comparison with the histological drawings they seem to demonstrate the incapacity of the camera to reproduce successfully histological sections. In the selection of their matter the authors have shown sound judgment, not only as to inclusion and exclusion, but also in the allotment of space. Their attitude towards matters still the subject of debate is particularly laudable; in all cases where diverse views are held, the authors have never hesitated to say so, and have gone to considerable pains, succinctly but with perfect fairness, to set forth all the conflicting views worthy of consideration. In one or two instances, as in the case of the alleged relationship between "intestinal stasis" and chronic mastitis, they have gone so far in their desire to be strictly impartial as to include hypotheses hardly meriting serious consideration. It is indeed on this subject of chronic mastitis that the reader looks in vain for guidance. From the two brief pages allotted to it no idea can be gained of the multiplicity of its clinical forms or histological appearances. The section on the blood is also disappointing. It does not help to clear thinking to describe "azurophile granules" as characteristic of the monocyte. It is true that the fine granules of these cells are azurophile, but they are seldom or never seen as such by the student, while the scanty but coarse azurophile granules of the large lymphocyte must be familiar to anyone who has seen a properly stained blood film. But these are relatively small points for consideration in a future edition.

The book may confidently be recommended alike to teachers and students of surgical pathology.

Laboratory Diagnostic Methods. By John A. Kolmer, Professor of Pathology and Bacteriology in the Graduate School of Medicine of the University of Pennsylvania; and Fred Boerner, Associate in Bacteriology in the Graduate School. London and New York: D. Appleton and Co. 1925. Pp. 338. 10*s.* 6*d.*

This book stands out from others of its class because its originators have from start to finish written solely for those actually concerned with the technique of clinical laboratory diagnosis. No cognisance is taken of the indications for the use of the various procedures described, nor is there a word as to the interpretation of results. Thanks to this rigorous self-limitation, the authors have been able to include details of methods covering practically the whole field of bacteriology, chemistry, and immunology as applied to clinical diagnosis. Histological methods of diagnosis are not included. Procedures are clearly and concisely described, for the most part in a series of numbered steps, and the composition of all reagents mentioned is fully set forth. The book should therefore prove of great value to all actively engaged in laboratory work.

The value of the book to medical practitioners and students, to both of whom it is addressed, is more doubtful. The busy practitioner has little time for the minutiæ of laboratory work. To place such a book as this in the hands of students would encourage the existing tendency to regard pathology as a short cut to diagnosis instead of the fundamental stuff of medicine. For the laboratory worker, who has presumably mastered the elements of his subject, and for the laboratory assistant to whom correct technical performance is an end in itself, the work should prove invaluable. Many of the methods described have not hitherto been available in any text-book. An excellent feature is the inclusion of McFarland's nephelometric method for the standardisation of bacterial vaccines; this closely resembles that described in 1919 by Kirman and Brown, but has the advantage of greater simplicity. It would mark one step in the clearing of the tangled skein of vaccine therapy if some such method as this could gain universal acceptance. At present one man's million may be another's thousand so far as organisms are concerned. Given a standard nephelometric method, the user of a vaccine could be reasonably sure that his "million" always represented the same amount of bacterial substance, though the actual figures would remain as mythical as at present.

PÆDIATRICS.

Handbuch der Kinderheilkunde. Third edition. Vol. IV. Edited by Prof. M. von Pfaundler, Munich, and Prof. A. Schlossmann, Düsseldorf. Leipzig: F. C. W. Vogel. Pp. 789. M.45.

The third edition of this well-known handbook is completed by the appearance of the fourth volume, which contains the index to the whole work. In the first part of the volume Prof. Noeggerath and Dr. A. Eckstein deal with the diseases of the urogenital tract and of the suprarenal glands, which are described in considerable detail, and preceded by a really useful account of the physiology and chemistry relevant to the subject. With the exception of a short chapter by Dr. J. Husler on bone and joint diseases, the remainder of the volume is devoted to neurology, and these chapters, by Prof. Ibrahim, Prof. Gött, Prof. Sage, and Dr. Mendelssohn, form one of the most comprehensive works which have appeared on this branch of children's disease. While they should be invaluable as a work of reference, their utility is of wider application. The chapter by Prof. Gött on functional nervous disease contains much that is original in its presentation, and should be read by all who are interested in this subject. One may regret the somewhat arbitrary division into separate chapters on organic and functional diseases (the latter including chorea, epilepsy, and mental defect) by different authors, but this does not detract from the excellence of the articles. The well-established reputation of this handbook will certainly be maintained by the new edition.

DIETETICS.

The Diabetic Life. By R. D. Lawrence, M.D., Chemical Pathologist and Lecturer in Chemical Pathology, King's College Hospital. London: J. and A. Churchill. 1925. Pp. 161. 7*s.* 6*d.*

This book has been written to meet the needs of both patient and doctor. It is quite certain that if the diabetic patient wants to keep well he must know a good deal about his disease. The book is well suited for this purpose. The elements of physiology and the symptoms of the disease are set out very clearly. The necessity of making the diet as palatable as possible is clearly recognised throughout. Provided that the patient has sufficient intelligence, he can be told to arrange his diet himself according to the number of grammes of carbohydrate, protein, and fat which are allowed him. The tables originally prepared by Drs. Harrison and Lawrence are included in the book and will enable the patient to make his own calculations. For those who are less intelligent the "line ration" scheme devised by Dr. Lawrence is simple to understand and should give sufficient variety. The different aims in treatment are briefly considered, and Dr. Lawrence does not consider that it is essential to make the patient uncomfortable in order to keep the fasting value of the blood-sugar normal. The sets of rules given for the use of insulin and for maintaining the general health are sound, and the appendix contains useful notes on food substitutes. The index is a good one.

The book should be of use to practitioner as well as patient.

Lexikon der Ernährungskunde. By Dr. E. MAYERHOFER and Dr. C. PIRQUET. Vienna: Julius Springer. 1924: Lief. I. Pp. 144. Sch.8.00. *1925: Lief. II. Pp. 330.* Sch.11.00.

THIS work, of which the first two sections (A to G) have appeared, represents a highly original idea carried out with remarkable thoroughness. It may be described as an encyclopædia of all that appertains directly or indirectly to the feeding of man or beast. It contains articles not only on every form of foodstuff and fodder, but on many subjects, the connexion of which with nutrition appears somewhat remote. Ants, for instance, receive notice owing to the peculiar habits of certain South American tribes; an article on apes appears for a similar reason, with some comments on the ethics of this form of diet. Short biographical notices are accorded to writers on gastronomic subjects, such as *Athenæus* and *Bergius* Benegt. In the articles on the more important forms of food special attention is given to nutritive values and methods of preparation. Some of the subjects, such as diet in fever, and the arrangement of children's diets, are intimately connected with medical practice.

This lexicon contains much that is quaint and rare, as well as much that is of practical importance to-day. It should be of use and interest to students of many subjects, more particularly to physiologists and physicians.

The Normal Diet. By W. D. SANSUM, M.S., M.D., Director of the Potter Metabolic Clinic, Department of Metabolism, Santa Barbara Cottage Hospital, California. *London:* Henry Kimpton. 1925. Pp. 72. 6s. 6*d.*

THE author of this little book considers that too little attention has been paid to the bulk requirements, the mineral and water requirements, and the balancing of a diet so as to avoid acidosis, and he has dealt with these more particularly while giving a brief account of the fundamental principles concerned with caloric value, protein and vitamin contents of a normal diet. His views on bulk requirements are the most original, and he appears to hold that colitis is about the most frequent cause of abdominal discomfort which may be largely removed by correct dieting. His statements on the progress of food through the bowel are, however, not in accord with the usual teaching in this country. He states that "the food taken on any particular day furnishes the residue for the bowel movement of the third or fourth day," while Hurst has shown by means of X rays that ingested food enters the rectum within 18 hours. For the average person to secure normal bowel movements Dr. Sansum considers that two pounds of fruit and vegetables are required daily, which is certainly more than the average person normally consumes. His views on acidosis are rather curiously stated, but they do serve to bring out an original idea on the subject of what he calls "shopper's headache," which occurs in women who do a full day's shopping on an empty stomach, thereby utilising much of their own fat with a resulting acidosis.

KLINISCHE LABORATORIUMSTECHNIK.

Second and enlarged edition. Vol. II. By Prof. Dr. THEODOR BRUGSCH and Prof. Dr. ALFRED SCHITTENHELM. Berlin: Urban and Schwarzenberg. Pp. 683-1418. G.M. 21.60.

IF this volume is intended for use in the clinical laboratory, as its title would lead one to suppose, the reader is tempted to speculate as to what kind of place a modern German clinical laboratory must be. Were only a quarter of the investigations described to be employed, this laboratory could only be worked by an amalgamation of the pure chemical, physical, biological, and mathematical departments of a very well endowed university. The "clinical laboratory techniques" include, amongst many other operations, the following: A complete account of inorganic analysis, a detailed account of ultimate organic analysis by means of both micro and macro furnaces, interferometric and refractometric observations on sera; detailed accounts of the methods of setting up the Starling heart-lung preparation. And it must be fully understood that we have not gone out of our way to quote the most abstruse sections, and that the above list is merely a small sample of the varied techniques described.

For the use of the worker in a big department embracing all branches of bio-chemistry the volume has great merits. For instance, there is a very complete account of the methods for analysing blood, fæces, urine, and tissues for metals, poisons, and drugs. The section on basal metabolism and respiratory methods is very well written, and is admirably complete. As usual, the section dealing with hydrogen-ion concentrations is far superior to that in any English book, a reproach that some of our own workers should remove. Methods of blood analysis are dealt with very thoroughly, and it is a pleasure to see Folin's methods reprinted without the misprints of his original papers. The volume contains methods for estimation of anything in everything. It is a boiled-down and condensed Abderhalden's Biochemische Handlexikon, with parts of the Arbeitsmethoden thrown in, all superimposed upon a background of Neubaem-Huppert's "Analyse des Harns."

The descriptions are good and full of detail, and an attractive feature is a series of tables, giving every factor likely to be wanted in the course of arduous biochemical research.

STUDENTS' GUIDE TO OPERATIVE SURGERY.

By ALFRED T. BAZIN, D.S.O., M.D., Assistant Professor of Surgery and Clinical Surgery, McGill University. Montreal: Renouf Publishing Co. Pp. 126.

THIS small book is for the use of students whilst actually performing operations upon the cadaver. The descriptions of operations are made as short and succinct as possible. The author makes no pretence of having written a text-book on operative surgery, and the work will be a useful guide to undergraduates doing an operative surgery course and perhaps also to their teachers, as a chapter on the organisation of the class and a schedule of the suitable operations have been added.

CHEMISTRY.

A System of Physical Chemistry. Third edition. By WILLIAM C. MCC. LEWIS, M.A. R.U.I., D.Sc. Liverp., F.Inst.P., Brunner Professor of Physical Chemistry in the University of Liverpool. In three volumes. Vol. III.: Quantum Theory. London: Longmans, Green and Co. Pp. 407. 15s.

THE first edition of this work was published in 1916 in two volumes. In the second edition in 1919 a third volume was added. This arrangement has been adhered to in the third edition. There are nine chapters, and a series of appendices, written by Mr. James Rice, Mr. A. McKeown, and Mr. R. O. Griffith on subjects with which they are specially conversant. The first chapter deals mainly with the theory of probability. The descriptions are admirably clear, and can be followed a priori. What is more, the mathematical parts are evolved before the readers' eyes, and no stages, however simple, are jumped. There is, perhaps, one minor point for criticism. The author explains very clearly that in ordinary mathematical probability the factor can never exceed unity. He states, in a footnote, however, that the factor for thermodynamic probability is usually a "quantity being in general a large integral number." This must confuse the beginner, since it would seem impossible to have anything surer than a certainty, which, after all, is what is meant by a probability factor of over one. The meaning of thermodynamic probability is fully described on p. 11, where the work of Boltzmann is discussed. We feel that a reference to this page would have helped the beginner. In the succeeding chapters the theories of quanta are reviewed, and a very full account is given of Planck's radiation hypothesis. The author is to be congratulated upon the clarity of his style and the clearness of his mathematical reasonings. The appendices uphold the high standard of the general text, with the result that the whole work can be described as a brilliant exposition of an intricate subject.

A Manual of Practical Chemistry for Public Health Students. Second edition. By Alan W. Stewart, D.Sc., A.I.C. London: John Bale, Sons and Danielsson, Ltd. Pp. 83. 5s.

The present edition appears after a lapse of 11 years, during which time the author states that he has "gained much experience in teaching students." The truth of this statement can easily be seen from the author's clear style and excellent arrangement. The book is meant purely as a laboratory notebook of methods, and is consequently interleaved. There are six parts, the first dealing with acidimetry and alkalimetry, the second with air, and the third with water analysis. All the descriptions of techniques are complete in themselves, and, with the exception of methods of air analysis, are up to date. The author does not mention certain modern advances in gas analysis—such as Haldane's methods, or the commercial use of the katharometer. The last three sections deal with analysis of food and beverages, disinfectants, and microscopic work. A series of examination questions are appended. Although the book is so small the descriptions are adequate, and practical wisdom is manifest in the hints to students in the front of the volume. The last hint consists of the one word "think."

PATHOLOGICAL ANATOMY.

Pathologisch-Anatomische Sektionsmethode nach den Grundsätzen des pathologischen Institutes der Prager Deutschen Universität. Herausgegeben von Dr. Béla Halpert, mit einem Geleitwort von Prof. Dr. A. Ghon, Vorstand des Institutes. Wien: Julius Springer. Pp. 48. G.M.2.

In this book is set forth in the briefest and most succinct manner possible the mode of procedure adopted in the performance of post-mortem examinations in the pathological department of the German University at Prague. To publish this procedure, the result of experience gained at many thousand autopsies, was distinctly a bright idea on the part of the author. The perusal of his pages in which is set forth the steady and methodical march of the investigation into the remotest recesses of the cadaver will cause many a pathologist to formulate good resolutions for the future. This is a book of a type of which, to the knowledge of the reviewer, there is no example in English. Although the procedure, modelled on that of Rokitansky, is not that in general use in this country, it would stand imitation.

PSYCHIATRY IN PRACTICE.

La Psychiatrie en Clientèle. By Dr. René Charon. Paris: A. Maloine et Fils. Pp. 152.

This small volume, one of a series dealing with various departments of medicine under the title "Comment guérir," is more completely divested of any academic superfluities than any other similar work which has come before us. Introduced by a brief résumé of normal and abnormal psychology, it presents the whole field of insanity under broad symptomatic headings, which are subdivided in the text only to the extent necessary for preventing confusion between maladies of totally different nature and origin. Some of the effects of this policy are necessarily odd: general paralysis, for instance, is treated in the chapter on "involutive disorders" (as distinct from "evolutive," due to congenital defect), as also is dementia præcox, apparently because both are dementias, and dementia is an involutionary change in senile cases. The whole is written from a practical standpoint, with concise and frequent paragraphs on treatment. In addition to the usual section on medico-legal questions, there is considerable space devoted to the sociological aspects of "mental hygiene."

New Inventions.

PHILIPS "METALIX" X RAY TUBES.

About a year ago we described in these columns[1] a new piece of X ray apparatus made by the firm of Philips, of Eindhoven, Holland, which had been in use at Dr. Bronkhorst's tuberculosis sanatorium in Apeldoorn. This apparatus, the Philips "Metalix" tube, has now been placed on the British market, and was exhibited at the International Congress of Radiology held at Westminster in July of this year, where it attracted considerable attention. The virtue of this apparatus lies in the simplicity of its manipulation and in the elimination of the danger to the operator hitherto associated with the application of X rays. The apparatus, which is made in five sizes for different types of work, consists of a cylinder varying in length from 16 to 20 in., in diameter from 2½ to 2¾ in., and in weight from 5 to 6 lb. The metal wall of the tube consists of a chromium-iron alloy capable of being readily sealed to the glass and retaining a perfect vacuum. The heat conductance of this metal is so very small that it can be made red-hot at one end without injuring the seal at the other end. An incandescent cathode filament is placed within the metal vessel which has a circular opening, at a very short distance from which an insulated electrode is mounted, serving as an anti-cathode. The electrons are drawn towards the anti-cathode through this opening. Thus a sharply-focused spot is produced, the diameter of which depends upon the size of the opening, which serves as an electron diaphragm. The X rays issue from the anti-cathode through a window at the end of the tube. The rays which do not emerge from the window are absorbed by metal protective walls of lead and brass arranged round the tube inside the chromium-iron casing; hence the tube can be used without any further protective devices. It is claimed that this type of tube, in addition to the general advantage of complete protection without external aids, also has an increased output as compared with the usual X ray tubes. The metal-encased tube has been developed in several types for various purposes, and such tubes are said to have worked perfectly satisfactorily for three years.

The "Metalix" tube was awarded the highest honours at the recent medical exhibition held in Warsaw on the occasion of the July Congress of Polish doctors.

Further particulars may be obtained from Philips Lamps, Ltd., 60, Wilson-street, Finsbury-square, London, E.C. 2.

THE LONDON
MEDICAL EXHIBITION

Organised by the Management of the Exhibition of the 17th International Congress of Medicine, 1913, and the Fifth Clinical Congress of Surgeons, 1914.

THE CENTRAL HALL, Westminster, S.W.

Monday, Tuesday, Wednesday, Thursday, and Friday,

OCTOBER 5, 6, 7, 8, and 9, 1925.

From 12 noon till 6.30 p.m. daily.

THIS Exhibition, established in 1905, has proved, in view of the large number who visit it annually, to be greatly appreciated. Its scope has been enlarged and covers the whole range of agencies for medical treatment to-day. The most recent organo-therapeutic, bacteriological, and pharmaceutical remedies and prophylactics; electro-therapeutic apparatus; scientific dietary; surgical instruments; hospital furniture and medical appliances; diagnostic material and apparatus; pathological and physiological apparatus; artificial limbs, aids in invalidity and deformity; sick room requisites; natural and artificial hydrotherapy; professional literature; hygienic clothing, &c.

The attendance is strictly confined to the Profession, and the public are not admitted. Last year the Exhibition was visited by several thousand medical and surgical practitioners.

A handsome Reception Room, where catalogues and other literary professional matter can be obtained, will be at the service of the Profession; also a spacious Tea Room in which light refreshments will be provided and where an orchestra will perform each day.

Invitation cards will be sent to every member of the Profession residing within a 50 mile radius of the Hall. Those in the Provinces who do not receive cards, desiring to visit the Exhibition, can obtain same on application to the Secretary, the London Medical Exhibition, 194–200, Bishopsgate, London, E.C., or at the Central Hall during the Exhibition week.

PRESS OPINIONS.

"The Lancet," Oct. 11, 1924—

"At the Medical Exhibition organised by the management of the Seventeenth International Congress of Medicine, 1913, and the Fifth Clinical Congress of Surgeons, 1914, in the Central Hall, Westminster, London, S.W., which opened on October 6 and closes to-day (Friday), a most informative collection of drugs and appliances used in the art of medicine and surgery, organo therapeutic, bacteriological and pharmaceutical remedies, electro-therapeutic apparatus, and many ancillary agencies, such as dietetics, and hospital and invalid furniture, were displayed. The medical man is essentially a student, but in these days progress is so rapid that even the attendance at post-graduate courses hardly suffices to keep the practitioner abreast of present-day treatment. An exhibition of this kind affords an opportunity to the busy practitioner to see the products and inventions which follow so closely on advances in treatment or technique, and to appreciate the labours of the various firms who, in response to the scientific requirements necessitated by research, administer to the needs of medicine and surgery. That the exhibition really fills a need is shown by the large number of medical men who visited it between the hours of noon and 6.30 p.m. each day, and by the keen interest which they took in the exhibits. In addition, the exhibition afforded an opportunity for friendly discussion and social intercourse, for which arrangements were made by the organisers, while the presence of many foreign and overseas visitors, some 300 of the latter having applied for tickets, showed the wide appeal of this display of scientific medicine and surgery."

"The Medical Press," Oct. 15, 1924—

"The 14th of the series of the London Medical Exhibitions was held at the Central Hall, Westminster, London, from October 6 to 10. The attendance, which was exceedingly good, was confined to the medical profession, the general public not being admitted, and several thousands of medical men from all parts of the kingdom found ample to interest them in the displays made by the leading firms. The Exhibition, year by year, has become more professional, the exhibits being, so to speak, more technical, expressing the latest adaptations of medical discovery and the newest in remedies and appliances created by the specialists of the manufacturing houses, many of whom hold high scientific qualifications. It was noticeable on this occasion that the exhibits demanded more than one visit from many members of the medical profession, and there can be little doubt from the repeat inspections that practitioners found many of the demonstrations not only interesting and educational, but of immediate application in practice. Among the attendance during the week was a goodly number of medical men from Overseas, the Government Departments, embassies, legations and agents-general in London, co-operating to bring the Exhibition to the notice of those on leave in this country. Without particularising, it seemed to us that the Exhibition served to emphasise the importance electricity in various forms is taking as a therapeutic agent; some of the installations were on a big scale, although, having regard to the construction of the appliances they are not expensive. The range of organo-therapeutic substances now at command was also brought out, as well as the variety and excellence of surgical instruments. We need not speak further of the many new introductions resulting from laboratory research in chemistry, pharmacy, dietetics, bacteriology, &c., nor of the advances in radiological apparatus and hospital and operation theatre equipment; but we may conclude this brief review by remarking on the up-to-date treatments given at the several British spas to-day."

LEWIS'S PUBLICATIONS

READY NEXT WEEK. EIGHTH Edition. With 6 Plates and other Illustrations. Demy 8vo. 12s. 6d. net; postage 9d.

PUBLIC HEALTH LABORATORY WORK

(CHEMISTRY)

By **HENRY R. KENWOOD**, C.M.G., M.B., D.P.H., F.C.S., Emeritus Professor of Hygiene in the University of London; Medical Officer of Health and Public Analyst for Stoke Newington, &c.

SEVENTH Edition. Thoroughly Revised. With 2 Plates and 90 Illustrations. Demy 8vo. 20s. net; post. 9d.

HYGIENE AND PUBLIC HEALTH

By **LOUIS C. PARKES**, M.D., D.P.H. Univ. of London, Lt.-Col. R.A.M.C. (Temp.); Consulting Sanitary Adviser to H.M. Office of Works, &c.; and **HENRY R. KENWOOD**, C.M.G., M.B., F.R.S.Edin., D.P.H. Lond., Chadwick Professor of Hygiene in the Univ. of Lond., Medical Officer of Health and Public Analyst of the Metropolitan Borough of Stoke Newington, &c. [*Lewis's Practical Series.*

"The new edition of this well-known volume will deservedly hold its own in popularity as a text-book for public health students."—THE LANCET.

With 14 Coloured Plates and 435 Illustrations (including 66 Plates in the Text). Royal 8vo. £2 10s. net.

DISEASES OF THE SKIN:

A Text-Book for Students and Practitioners.

By **J. M. H. MACLEOD**, M.A., M.D., F.R.C.P., Physician for Diseases of the Skin, Charing Cross Hospital; London Hospital for Tropical Diseases, and Victoria Hospital for Children; Lecturer on Dermatology, London School of Tropical Medicine, &c.

". . . One of the most important books on Dermatology produced in this country in recent years . . . singularly complete. The author is to be congratulated on his work, which is a credit to British Dermatology."—BRITISH MEDICAL JOURNAL.

SIXTH Edition. With Plates from Original Drawings (6 in Colours) and other Illus. in the Text. Demy 8vo. £2 2s. net.

ON DISEASES OF THE LUNGS AND PLEURÆ

Including TUBERCULOSIS AND MEDIASTINAL GROWTHS.

By **Sir RICHARD DOUGLAS POWELL**, Bart., K.C.V.O., M.D. Lond., F.R.C.P., Physician-in-Ordinary to H.M. the King; Consulting Physician to the Middlesex and Brompton Hospitals; and **Sir PERCIVAL H.-S. HARTLEY**, C.V.O., M.D. Camb., F.R.C.P., Physician, St. Bartholomew's Hospital; Senior Physician, Brompton Consumption Hospital, &c.

". . . can be confidently recommended as a safe guide to the practitioner in search of authoritative medical opinion in this country at the present time."—BRITISH MEDICAL JOURNAL.

EIGHTH Edition. With 14 Plates and 197 other Illustrations. Demy 8vo. 22s. 6d. net; postage 9d.

LEWIS JONES'S MEDICAL ELECTRICITY:

A Practical Handbook for Students and Practitioners.

Revised and Edited by **LULLUM WOOD BATHURST**, M.D.Lond., late Physician in Charge of the Electro-Therapeutic Department, Royal Free Hospital (Officers' Section); late Chief Assistant, Electrical Department, St. Bartholomew's Hospital, &c.

"All the chapters show the hand of revision and the addition of the new material of the past three years."—BRITISH MEDICAL JOURNAL.

SECOND Edition. With 31 Figures. Crown 8vo. 6s. net; postage 3d.

The CLINICAL EXAMINATION of the NERVOUS SYSTEM

By **G. H. MONRAD-KROHN**, M.D. Christiania, M.R.C.P. Lond., M.R.C.S. Eng., Professor of Medicine in the Royal Frederick University, Christiania, &c.

With Foreword by T. G. STEWART, M.D.

"We have no hesitation in recommending it to medical students and practitioners."—GLASGOW MEDICAL JOURNAL.

SECOND Edition. Crown 8vo. 5s. net; postage 4d.

THE SYSTEMATIC TREATMENT OF GONORRHŒA IN THE MALE

By **NORMAN LUMB**, O.B.E., M.B. Lond., F.R.C.S. Eng.

". . . The book is sound in principal and lucid in exposition, and can be recommended to practitioners and students as a useful guide."—MEDICAL PRESS.

THIRD Edition. With 6 Illustrations. Fcap. 8vo. 4s. 6d. net; postage 2d.

PRACTICAL FORENSIC MEDICINE.

A Police Surgeon's Emergency Guide.

By **C. GRAHAM GRANT**, V.D., L.R.C.P. & S.Edin., Barrister-at-Law (Gray's Inn), Clerk of Arraigns, Central Criminal Court, &c.

With a Chapter on Fees by Sir HERBERT AUSTIN.

". . . information of a practical type . . . a wealth of sound advice. The material is well arranged."—THE LANCET.

OPIUM AS AN INTERNATIONAL PROBLEM.

The Opium Committee of the League of Nations recently concluded its discussion of the annual reports from various States. The notes published in The Lancet from time to time[1] have shown how difficult is the problem with which this Committee is grappling. Since The Hague Convention of 1912 the control of the traffic in dangerous drugs has been a matter of anxious and prolonged discussion wherever nations have gathered in congress. The second League Conference held 28 sittings, and any definite results were prejudiced by the regrettable withdrawal of the American and Chinese delegates. Much difference of opinion now exists as to the value of the advances made. Prof. Perrot, a French delegate, writes with some satisfaction in the *Revue Scientifique* of July 11th, while Sir William Collins in the August *Contemporary Review* doubts whether the proposed Permanent Central Board may not prove a means of procrastination rather than an agent for forward movement. The idea of this Central Board originated in the Opium Advisory Committee of the League of Nations, and was endorsed by the United States and Great Britain. Its principal business would be to gather information about the production of, and international traffic in, narcotics, and especially to watch the channels of illicit trade smuggling. It was intended by those who devised the idea of this Central Board that it should have very wide and drastic powers of inquisition and publicity, and it was to be in a position to ration raw material and manufactured narcotics among the nations, with strict reference to their needs and available supplies. In the preliminary discussions, the American, British, and certain other delegations sought to give this Board such powers, but the obstruction encountered was sufficient to whittle down the proposed powers to an authorisation, in the event of an excessive and unexplained accumulation of narcotics in any country, and a belief by the Board that this country was in danger of becoming a centre of illicit traffic, "to recommend that no further exports of the substances covered by the present Convention or any of them shall be made to the country concerned until the Board reports that it is satisfied as to the situation in that country." The Board would also be authorised to publish a report in any such situation; and the Convention also declares it to be the friendly right of any country party to the agreement to draw the attention of the Board to any matter which appears to it to require investigation.

Writing in the September number of the *World's Health*, the journal of the League of Red Cross Societies, Mr. John Palmer Gavit, who until recently was managing editor of the *New York Evening Post*, and was a close observer of the conflict of interests in the winter of 1924–25, attaches considerable importance to this Board. He hopes that the Governments concerned will ratify the Convention, but a reply in the House of Commons on June 17th last indicated that no ratifications had so far been deposited. Mr. Gavit believes that, given the will and the necessary powers, the production of manufactured narcotics can be controlled. There is only one place where this can be done, and that is the place whence every ounce of morphine, heroin, and cocaine must emerge at the outset of its search for victims—namely, the factory. Drug factories are relatively few, and the Governments know exactly where to find them. The character of the problem has, he contends, changed greatly since international agreement was first registered in 1912. The evil is not now an exotic affair of the Far East—the eating, drinking, and smoking of raw and prepared opium are injurious enough, but they are surpassed by the present-day abuse of the derivatives of opium and other highly concentrated drugs of addiction. These, being less bulky and more easily disguised, are more profitable to smuggle. Also, they have behind them the push of the Western genius for business organisation, and the subtle effect upon conscience of absentee ownership. It is not generally realised that, since the Hague Convention and during and after the World War, the situation has developed with appalling swiftness. The old enemy, opium, in a new and immensely more venomous and devastating form, with new allies and in overwhelming quantities, has become a very real menace to civilisation. Mr. Gavit gives some interesting and disquieting figures. It will be remembered that the Health Commission of the League of Nations, the Opium Advisory Committee, and a mixed subcommittee representing both gave an estimate showing the amount of raw opium and crude cocaine needed per capita per annum for medical and scientific use by the population of the world within reach of modern medical service. This amount was 450 mg. of raw opium and 7 mg. of cocaine. On the basis of an estimated 744,000,000 (of the world's assumed total population of 1,747,000,000) as the population represented in the phrase "medical and scientific needs," the total legitimate needs of the world work out in tons as follows: 100 for medicinal opium, 136 for morphine, 84 for codein, and 15 for heroin—a total of 335 tons. After bringing up this total to 340 tons by allowing for such of the natives of Asia and Africa as might get access to doctors, Mr. Gavit writes: "But let us 'go the limit' and allow 450 mg. of raw opium a year for every man, woman, and child in the world. That will give us the outside total as the conceivable medical and scientific needs of the whole world of 786 tons of raw opium per year." What is the actual amount of opium produced? No one knows. But conservative estimates converge with remarkable closeness towards a total production of about 8600 tons, including 5000 tons attributed to China. In other words, less than one-tenth of the total amount of opium produced is for legitimate medical and scientific purposes. Still less is known about the output of cocaine, of which only little more than 5 tons a year would be needed for the 744,000,000 of the population of the world supposed to be within reach of modern medical service. But a clue can be given to the liberality of the supply actually available by the fact that Japan alone in 1922–23 manufactured 15,432 lb. (*Times*, August 27th). It is evident, therefore, that the production of narcotics in the world is at least ten times as great as the most extravagant estimate of its legitimate needs.

While we wait for the efficient Government control of the drugs of addiction, it is to be hoped that voluntary associations, such as the national Red Cross Societies, may take up the educational side of the problem, teaching the public the nature and the immensity of the narcotic peril. Such a campaign would not only educate the public, but would also probably convert some of the static power of Governments into kinetic energy.

◆

THE METROPOLITAN ASYLUMS BOARD.[1]

The annual report of the Metropolitan Asylums Board, which has just appeared, contains, as usual, a large amount of well-arranged information concerning the treatment of infectious diseases in the important area of its work, and it is to this section that the main attention, both of the medical profession and of the public, will be paid. The responsibilities of the Board, however—and it is sometimes forgotten—are of a much wider range than this section indicates. If we include the work in tuberculosis done by the Board under the heading of the care of infectious diseases, there still remain some six other principal directions in which services are discharged which are invaluable to the public; for the duties of the Board include the management of hospitals and institutions for children suffering from specified contagious diseases as well as for those requiring special treatment in hospitals or convalescent homes; the provision for certain classes of mental defectives and epileptics; the care of Poor-law lads in training for the sea, both for the Navy and the mercantile marine; while a certain proportion of the casual poor fall under their jurisdiction as an authority which was instituted more than half a century ago by an order of the then Poor-law Board. Arrangements have been made only this week with the Ministry of Health, under which cases of puerperal fever to be referred to the Board are to be grouped in certain hospitals for special care and study. The Board also furnishes London with ambulances. Under these headings this report makes a clear statement of work done and results obtained, and it is possible that the figures in connexion with the last-named activity will be a surprise to many, having regard to the frequent complaint that the metropolis is lacking in proper facilities for the transport of the sick. The ambulance service, by land and river, of the Board during the year in question, dealt with over 72,000 removals, an increase on the previous year of 10,000, while the distance covered in the combined journeys amounts to a total mileage of 725,000 miles, being an increase of about 40 per cent. over the mileage of the previous year. This increase is indicative of a growing practice on the part of the medical profession and the general public to employ the ambulances of the Board in lieu of less specialised means of transport for the conveyance of patients and invalids over considerable distances. This willingness to use the ambulances of the Board accentuates the fact that public comments on the dearth of ambulances in London nearly always have the same origin; they are aroused by some default in dealing with cases of accident in the street. The whole of this question has been under anxious consideration for some time, and was referred by the Minister of Health over two years ago to the Voluntary Hospitals Commission, when a conference was held on the position of ambulance services generally in the metropolitan area. The need for better organisation and supply of transport of the sick should be better met, and it is to be hoped that action is approaching.

The section dealing with infectious diseases leaves a rather mixed impression of satisfaction and the reverse, when we study the record of progressive work in the metropolis to provide for the treatment of the epidemic group. The story of scarlet fever is a cheerful one; it can be seen from the figures that the disease can now be regarded as one which is normally unlikely to end fatally, the case-mortality is considerably under half what it was 30 years ago, while the notifications are less, though the average population of the area concerned is greater by some 80,000 persons. Measles must always be a difficult disease to summarise in statistical terms, because of its sudden incidence in large epidemics and their rapid cessation. Further, the Board deals only with a proportion of the cases, as accommodation for measles is found elsewhere during the early stage of an outbreak, the demand for hospital treatment only occurring after a certain limit has been reached. Therefore an epidemic may make grave demands on the accommodation of the Board suddenly, which demand declines with proportionate rapidity. Reference to the statistical table supplied in this report will show how the help of the Board is sought with increasing urgency for brief periods, during epidemics of measles, and how promptly the need for assistance dies away. The figures for small-pox are satisfactory, the past year being the twenty-third in succession since the disease has secured any firm hold throughout the metropolitan area. A brief history of small-pox in London, so far as the activities of the Board have been concerned, is included in an appendix, and would make salutary reading at the present moment for a good many persons. The references to encephalitis lethargica are significant, and are supported by a note on the arrangements which have been secured for the treatment of cases, written by Dr. Gordon Pugh, chief medical officer of the Children's Service of the Board. The note shows that the need for institutional treatment in juvenile cases of encephalitis lethargica is great and may be increasing in urgency, having regard alike to the recent extension of the disease in London, the non-existence of facilities for dealing with the cases, and the special difficulties incidental to the mentality of patients in the later stages. During the second quarter of 1924 there was a high notification rate of the disease, 391 cases out of 611 occurring during that quarter, while it is now recognised that, quite apart from its intrinsic seriousness, apparent cure of the disease is frequently followed by obscure after-effects, developing into physical, and especially psychical, disturbances of an anxious nature. Abnormalities of conduct have been observed which might bring, and which possibly have brought, patients within the sphere of the criminal law, when their actions have been dictated by the remaining influences of the disease, and this is a state of affairs to the remedy of which attention should be directed at once.

We refer, finally, to the anxious position revealed by the figures in relation to diphtheria, whose prevalence is sometimes regarded with complacency because the antitoxin treatment, devised 30 years ago, produced such wonderfully favourable results. But steady though the progress, which can be recorded, may have been in the treatment of diphtheria, it has been too slow, for the figures show that, in London at any rate, the forces of the disease have latterly been gathering power. Compared with the septennial period 1897–1903, the septennial period 1918–1924, gives only superficially the idea of any progress at all, and none whatever is claimed in the report. The number of notifications, though higher in the latter of these periods, is not out of proportion to the increase which has taken place in the average population, and the death-rate per cent. is in the same period only still what it was in the earlier period. But in the intermediate 14 years the notifications were much less numerous, while figures indicating the seven year rate per 1000 persons living are considerably higher for the last septennial period than for the two preceding periods. The statistics and the words of the Board alike show that the offensive power of diphtheria is increasing in greater ratio than the defence, and it would seem that we have been lulled into inactivity by the gratifying experiences which followed the introduction of the antitoxin treatment. The fact that the position to-day is infinitely better in respect of diphtheria than it was 30 years ago is a legitimate source of satisfaction. In the matter of case-mortality a steadily declining rate reached its minimum in 1924. This is the lowest figure on record and proves, if proof were wanted, that the use of antitoxin has saved untold lives. But the continuance of a high attack-rate in the metropolis calls for anxious thought. It seems to the Board that the time has come for the adoption of measures calculated to restrict more effectively than hitherto the depredations of the disease, and in this connexion the recent figures for New York City, which are quoted in the report, should be studied by those taking an active part in the maintenance of public health. All will agree with the opinion of the Board that a case has been made out for strict consideration.

SUGAR AND ATHLETICS.

THE most entertaining function of modern scientific discovery in the departments of applied physiology, domestic science, and the like is to find out *not* what we ought to do, but why we do what we do. We know now—more or less—why we should eat cabbage; we know why a man cannot run a mile as fast as he can run 100 yards and cannot hope to do so; we have a rationale for loafing in the sun. We do not know why we use soap to clean ourselves with, nor how to wash woollen socks without shrinking them; science has addressed itself to these problems, but has failed to find a solution satisfying to the housewife. No serious attention appears to have been given to the problems of why no one can eat rabbit daily, and why a white silk shirt must not be dried in the open like a cotton one for fear it will go yellow. Still, much has been and more will be discovered, and we may expect in time a due recognition by the public who are curious about dietetics of the renaissance of healthiness which emerged from the discovery by the Dutch of cabbages which would stand the winter. There has been going on the annual lamentation at the lack of interest shown by the general public in the proceedings of the British Association for the Advancement of Science. The truth no doubt is in the first place that the public takes a great deal more interest in the Association than the Association thinks, while in the second place real scientific discoveries leave the public moderately unmoved, because they do not concern their familiar activities. It is very good to know about the shape and balance of the earth, or why the amoeba is of a more useful size than the rhinoceros, and it is wonderful that mere men should be able to find out such things, but these discoveries do not make much obvious difference to life, and most people would prefer a solution of the sock problem. A naïve contribution to the explanation of our habits is recorded[1] by Dr. S. A. Levine and his colleagues at Harvard. They found last year that some of the runners in a Marathon (or marathon—they print the word indifferently, and it is a nice point) who were particularly exhausted showed an abnormally low blood-sugar and symptoms comparable to those of an overdose of insulin. On further analysis it appeared that exercise such as running first somewhat increases the blood-sugar, but the percentage afterwards drops back to normal, at which it remains until, in some individuals, a further fall appears about the time when they get profoundly tired. On a repetition of the race this year these observers confirmed their findings, and got some of the runners to demonstrate that eating candies was very reviving when exhaustion began to appear. It is interesting to know that physical exhaustion is associated with a low percentage of sugar in the blood, and we are led to wonder whether the same is true of the tired, sleepy state which supervenes when a maximum discharge of adrenalin enables the subject to have a really violent emotion. But the most curious thing is that neither the authors nor the subjects at Harvard seem to have been aware that the consumption of sugar in one form or another is very widely known as preventive and curative of fatigue. Those who believe that white lump sugar really is sugar and not some artifice of a deceitful manufacturer will take it in that convenient form; others pin their faith on a bull's-eye about the sixteenth hole; a long-distance cyclist will start out with a long stick of barley-sugar in his mouth, and gradually incorporate it; sugar cakes are a sine qua non at an athletic tea-party. We almost suspect that the Harvard Marathonians have been taking advice about their diet from physiologists—a very dangerous thing to do—instead of from their mothers. However well science may explain diet it is apt to choose it badly, because it neglects the accumulated sum of human prejudices in the field which interests mankind more than anything else.

◆

THE NEW CONCEPTION OF LEPROSY.

THE conception of leprosy as a progressive and inevitably fatal disease is one well established in popular and to a great extent also in medical opinion; but, as is pointed out in a recent article in the *Medical Journal of Australia* (July 11th, 1925), this conception is not necessarily founded on fact. Some 20 years ago Dr. G. H. Taylor, who is at present medical officer to the New South Wales Government railways, in a systematic investigation of the patients in the general wards of the Coast Hospital, New South Wales, pointed out that thickening and tenderness of the ulnar and peroneal nerves and slight anaesthesia of the parts supplied were not uncommon in individuals, in some of whom healed leprous lesions were found post mortem. Unfortunately, this work appears to have received little recognition in official quarters, while Dr. Taylor himself at that time did not recognise the grave danger to the community of such cases. The recent writings of E. Muir (THE LANCET, Jan. 24th, 1925, p. 160) certainly confirm much of Taylor's work, for he has demonstrated leprosy bacilli in many persons who do not manifest leprous lesions, and in others who appear to recover spontaneously. It therefore becomes apparent that Dr. Taylor's original conception of the disease is one of considerable historical value.

Annotations.

"Ne quid nimis."

THE NEW TUBERCULOSIS ORDERS.

STATISTICS compiled by Dr. Stanley Griffiths, of Cambridge, and other workers, both medical and veterinary, have demonstrated beyond dispute the dangers to child-life in this country from tuberculous milk, and for a long time it has been a crying disgrace that such milk should be sold without restriction. The situation will be somewhat improved from the first day of the present month onwards, for on that date an Order of the Ministry of Agriculture became law, by which the cow with the tuberculous udder (and its equally dangerous "visibly infected companion") is marked down for immediate destruction. For a long time the veterinary profession has, through the agency of the National Veterinary Association and its branches, been forwarding resolutions to the Ministry of Agriculture, the Ministry of Health, and other authoritative bodies asking that power might be given for the destruction of this very obvious source of danger, not only to its own kind, but also to man. The Animal Diseases Tuberculosis Order, 1925, illustrates well the value of coöperation between the human and the veterinary branches of medicine; the former to control the food of man and the latter to inspect and deal with its source of origin. Of the million tuberculous cows or thereabouts in Great Britain not all are used for dairy purposes, and those which are free from tubercle of the udder may not be an immediate source of danger to the milk consumer; yet at any moment the tuberculous dairy cow may become infected in its udder and pass on living tubercle bacilli in its milk. Under the terms of this Order every person having in his possession or under his charge (1) any cow which is, or appears to be, suffering from tuberculosis of the udder, indurated udder, or other chronic disease of the udder; or (2) any bovine animal which is, or appears to be, suffering from tuberculous emaciation; or (3) any bovine animal which is suffering from a chronic cough and showing definite clinical signs of tuberculosis, shall without avoidable delay give information of the fact to a constable of the police force for the area wherein the animal is, or to an inspector of the local authority, and the constable or inspector shall forthwith transmit the information to the local authority. The veterinary inspector is then empowered to order the destruction of the animal, allowing the owner a fair and mutually agreed sum as compensation. The premises are then dealt with as infected places, and the remainder of the herd also come under inspection. The main point, however, is that the cow with the tuberculous udder, and the cow which is obviously the subject of a general infection, is destroyed, instead of being, as was the case prior to the enforcement of this Act, allowed to be sold, either privately or in the open market, to disseminate her myriads of tubercle bacilli broadcast amongst her neighbours. The September issue of the *Veterinary Journal*, which is entirely devoted to public health work, contains an article by Prof. Gofton, chief veterinary officer to the City of Edinburgh, on the position of the veterinary profession in Scotland in regard to the inspection of milk and meat. Scotland has fully recognised the fact that it is the veterinary surgeon with his professional training in the diseases of animals who is the proper person to give an opinion as to when the cow and its products are suitable or otherwise for the food of man. The Public Health of Scotland Act, 1897, opened up the way for the utilisation of the veterinary surgeon in such work. The Milk and Dairies (Scotland) Act of 1914 imposed on him wider and more important duties in supervising the milk-supply, and a reinforcement of this Act, which also came into force on Sept. 1st last, gives the veterinary officer in Scotland power to order the destruction, not only of the cow with the tuberculous udder, but of any cow which is emaciated, has a chronic cough, or other symptom of severe tuberculosis.

SANITATION PAYS.

IN the annual report of the medical officer of health of the Port of Liverpool, a note on which we publish to-day, it is observed that the rat inspector is keeping down rat harbourage about the docks, that this involves some trouble and expense, but that some of the officials "even admit that it pays." In the July number of the *Military Surgeon* is a paper by Colonel H. C. Fisher, Medical Corps, U.S. Army, about the sanitary effect on the world of the methodical medical regulation of ships passing through the Panama Canal. He notes the educational effect of the risk of quarantine on neighbouring ports and on shipmasters. The former clean up their ports, the latter ask for rat fumigation, as they have now learned the comfort of being free of rats and other vermin. He adds, "We are receiving . . . words of commendation from shipping interests for the work done . . . shipping is realising that sanitation pays." Sir Malcolm Watson[1] calculated that certain estates in Malaya, employing 29,068 coolies, saved, through malaria prevention, £114,000 in one year, almost £4 per coolie, or 2*d.* per pound, or £3 10*s.* per acre on the cost of their rubber. It was estimated in the war that every man dead or invalided home from Palestine cost the nation £1000 for treatment and replacement. We have ourselves remarked that Lord Allenby's break through in 1918 was only made possible by reason of the malaria prevention of the preceding six months, and that to prevent the expected 60,000 fever cases due that autumn among the 70,000 men of that army did, in fact, cost only £40,000 (12*s.* per man), while treatment of the 60,000 would have cost £1 apiece for quinine alone. All who practise medicine have no doubt that sanitation pays, but there is still want of more economic and statistical teaching to drive this fact home into the minds of the public and of administrators at home. It is more fully grasped in the Empire overseas. Happily, the recent Public Health Act gave local authorities in this country greatly increased power to issue propaganda on health questions.

COLON LAVAGE.

ALTHOUGH injection of water into the bowel is an old and well-established medical practice the present technique of intestinal lavage is comparatively recent. The method known in England as the Plombières treatment was introduced by Dr. Maurice de Langenhagen about 27 years ago for the relief of muco-membranous colitis, and sprang into immediate popularity; since then, however, it has fallen into the disrepute which inevitably awaits a remedy too suddenly fashionable. Much criticism has almost led to its disuse in France; but in England the treatment retains many advocates, and is practised at Bath, Harrogate, Buxton, Llandrindod Wells, and other spas. At Harrogate, for instance, over 127,000 treatments have been given in the past ten years. Some interest will therefore be felt in the considered opinions, or "second thoughts," which Dr. de Langenhagen contributes to a symposium on Colon Lavage in the August issue of the *Archives of Medical Hydrology*. He attributes the failure of the treatment in the hands of his critics to a misunderstanding of his aims and technique. Lavage in colitis is to be regarded as essentially a *sedative* measure. The fluid is intended to act, not as an evacuant, but as an internal bath, which clears away mucus, reduces congestion at the orifices of glands, washes the mucous membrane, and reduces the excitability of nerve-endings. Any method which produces spasm or pain is inappropriate. The bowel is to be "persuaded" rather than stimulated, and to this end the injections must be small and must be made very slowly and at low pressure (12–16 inches). He recommends the use of weak (hypotonic) natural mineral waters, such as those of Plombières or Bath, or of plain boiled water with or without small quantities of common salt (7 per 1000) or bicarbonate of soda in solution. Medicated injections or strong mineral waters should not be employed, as they are likely to irritate the bowel. Two consecutive injections are given at a temperature of 110°–115° F., the first being rejected by the patient and the second retained for a few minutes. A sedative thermal bath or a warm application to the abdomen follows, and the treatment is not given more frequently than once every two or three days. Dr. de Langenhagen claims a measure of success for this treatment in at least 70 per cent. of cases of colitis, and whilst admitting that a certain number of people, perhaps 6 per cent., are intolerant of rectal injections—and in such cases they must be abandoned—he disagrees with those who say that lavage leads to constipation and atony, softens the intestinal wall, and increases the flow of mucus. Given with discretion, the treatment is neither dangerous nor hurtful. Another contributor to the symposium is Sir William Willcox, who states that he has found lavage of very great value in chronic colitis, and as a supplementary treatment in systemic diseases, such as arthritis and diabetes, in which colon toxæmia is an important causal factor. It may usefully be employed in private practice, and can be given by any intelligent nurse. Further contributors, describing the methods in use at Buxton, Harrogate, Bath, Chatel-Guyon, and other places, reveal a lack of unanimity which lends force to the plea that practitioners should carefully consider what may be the presumptive signs of intestinal toxæmia which justify colon lavage; how far liquefaction of the bowel contents affects toxin absorption; which cases require sedative and which require tonic lavage; and, lastly, what is the danger in any given case of adding to the morbid impressions of a nervous patient by local treatment.

LATHYRISM.

OF the forms of chronic poisoning with grain and vegetable food ergotism is probably the best known and most widely studied, although its occurrence, except in parts of central Europe, is something of a rarity. In certain districts in India, however, another form of grain poisoning, lathyrism, occurs with comparative frequency, and the disease has also been reported from Algiers, France, and Persia. This disorder, characterised by a spastic spinal paralysis, is usually ascribed to chronic poisoning by various kinds of common pulse, *Lathyrus sativus*, but recent research work by L. A. P. Anderson, A. Howard, and J. L. Simonsen [1] has shown in a striking manner that this is not the case. These workers had been struck with the fact that despite a popular theory associating lathyrism with an alkaloid in the seeds of *khesari*, the vernacular name for pulse, various chemical analyses of the seeds had given differing constitutions, some observers failing completely to find any poisonous bases in these seeds, while feeding experiments on animals had also given conflicting results. On further investigation it was found that the lathyrus crop was always contaminated with leguminous weeds, which were reaped and threshed with the pulse proper and the seeds of the contaminating plants very closely resemble the pulse seeds in appearance. A vetch, known as *akta*, occurring in samples of pulse from regions where lathyrism was prevalent, was particularly investigated, and it was discovered that while botanically pure *khesari* or lathyrus seeds contained no alkaloidal substances and were without any deleterious effects on animals, the reverse was the case when dealing with *akta*. Other weeds occurring in *khesari* fields proved harmless, so investigations were confined to the *akta* seeds. Chemical analysis showed that these seeds contained a substance called vicianin, closely related to amygdalin, and also a glucoside, vicin, which, on hydrolysis, yielded a sugar and a base divicine which proved to be an oxy-amino derivative of pyrimidine. Feeding experiments on ducks and monkeys were carried out, using pure *khesari* and contaminated specimens containing varying percentages of *akta*. The ducks received raw grain, both fresh and germinating, and the monkeys cooked pulse, various preparations being used to imitate the diet of the Indians. Careful control experiments were made to exclude starvation and vitamin deficiency, and the workers pronounce themselves absolutely satisfied that *akta* is the substance responsible for the production of symptoms in animals closely resembling lathyrism in humans. Divicine prepared by hydrolysis from vicin is toxic to animals in doses of from 0·4 mg. to 0·5 mg. per gramme of body-weight, and this is looked upon as the poisonous substance in *akta* responsible for the disease. It appears to be a comparatively simple matter to eliminate the contaminating weed from the lathyrus crop by a process of sowing *khesari* in lines a foot apart and removing the seedlings of *akta* in the early stages of growth. It should therefore be easy to prevent the occurrence of lathyrism in those districts where this disease has up to now been not infrequently seen.

AN AMERICAN CONVALESCENT HOME.

NEAR the city of White Plains, New York, there was established in 1915 an institution called the Winifred Burke Relief Foundation. Besides serving as a convalescent home for those discharged from hospitals, it was designed by the founder "for the relief of worthy men and women who, notwithstanding their willingness to support themselves, have become wholly or partly unable to do so by reason of sickness or misfortune." An account of the Foundation and its work has been published in THE LANCET,[1] and in the sixth report,[2] which has now been issued, there may be detected an undiminished ardour not wholly obscured to English ears by an unfamiliar vocabulary. The centre of the work is the home itself. It comprises 11 buildings standing in 60 acres of ground, and containing about 300 beds, which are divided amongst men, women, and the adolescent. The vast majority of the patients come from hospitals and dispensaries, but others are sent by private doctors, employers, and friends. A convalescent home of this kind, according to the report, "is an institution in the country which receives post-ill and preventive ambulant patients on medical diagnosis, and gives a short rest-exercise physical-mental upbuilding with nurse-medical care, sufficient to return them to normal or substandard life activities." This definition indicates one of the features which makes this home especially interesting. It aims at prevention as well as cure, and the directors believe that the pre-tuberculous, early cardiac cases, and many of those suffering from the milder grades of mental disorder and neurasthenia should be treated in such institutions. Twenty-five per cent. of the cases are chronic; but this is not considered good reason why they should be deprived of what benefit they can get. Convalescent homes on these lines are regarded by the Foundation as one of the most urgent medical needs of the United States, and it is suggested that they will solve a large number of problems. What, then, is the treatment at this model institution? "Homelikeness is not sought . . . a measure of frank institutionalism, with its democracy and anti-neurotic momentum, gives superior results." The individual is saved from his friends; "doctoring and doctor-thinking" are discouraged, and the attendants devote themselves to "courage therapy." Carefully prescribed games are interspersed with rest, and as the patients improve they undertake work in the garden or workshops, again according to prescription. They have to do none of the housework, and in this the institution compares favourably with some English convalescent homes, where tired mothers find a duller repetition of their home duties. In a word, it is clear that the success or failure of such a home depends not so much on organisation as on atmosphere. If indeed the heterogeneous patients "return to the surgeon and the social adjuster erect, colourful, courageous, crutch and whim-free persons," then the triumph is a personal triumph for the members of the staff. To read statistics of admission to this institution is to gain some idea of the number of foreigners in New York, and it is impossible not to sympathise with the ambition to make these largely undesirable elements fusible. In a convalescent home there exist golden opportunities to instil American ideals, and these are not missed at White Plains. But apart from this the Foundation is an interesting experiment, and is designed to solve problems which are English as well as American.

SCANDINAVIAN VIEWS ON RENAL TUBERCULOSIS.

IN 1923, at the fourteenth meeting of the Scandinavian Surgical Society, it was decided that in the interval between this meeting and the next, to be held in the summer of 1925, Scandinavian surgeons should collect their cases of renal tuberculosis and should provide a digest thereof for discussion at the fifteenth meeting. A scheme was drawn up, so that the same data should be provided by the different Scandinavian countries, and while Prof. P. Bull undertook to collect the cases from Norway, Prof. Rovsing was responsible for Denmark, Prof. G. Ekehorn for Sweden, and Prof. Runeberg for Finland. In a communication we have received from Prof. Bull we learn that the fifteenth meeting took place between June 25th and 27th of this year in Copenhagen. The papers which were read on this occasion (some of which he has kindly sent us) give a very favourable impression of the value of this system of pooling the experiences of a great number of surgeons who have been given plenty of time to collect and study their material. Prof. Bull's Norwegian material consisted of 580 cases collected by 21 surgeons; Prof. Rovsing's Danish cases numbered 632, provided by 31 different hospitals; Prof. Ekehorn's Swedish cases numbered 1498, reported from 22 different hospitals, and Prof. Runeberg's Finnish cases numbered 213, all of which hailed from Helsingfors. It is interesting to note how uniform is the experience of practically every surgeon in Scandinavia with regard to certain features of tuberculosis of the urinary tract. It would seem, for example, that in every Scandinavian country this is a disease which is confined to the third and fourth decades of life in most cases. In Prof. Bull's material, for instance, 74·7 per cent. of all the cases were observed in this age-period, and much the same observation was made in the other Scandinavian countries. His ratio of males to females was as 59 to 41, while the corresponding ratio for the Swedish cases was as 57·6 to 42·4. Prof. Bull found that 40 per cent. of his male patients suffered from tuberculosis of the reproductive system, but, curiously enough, this complication of the tuberculosis of the urinary tract did not greatly impair the prognosis. With regard to the complications of nephrectomy, he found infection of the operation wound, which occurred in 27 per cent., the most important, and he emphasises the seriousness of any step which, when taken during the operation, is calculated to infect the wound with tubercle bacilli. Recovery could be claimed for 51·6 per cent. of his cases in which nephrectomy was performed. We have in these lines given but the scantiest of summaries of these important papers, the contents of which might justly be called encyclopædic. It is to be hoped that means will be found to provide a translation of them into English, French, or German, so that the information they contain need not be limited to the countries of their origin.

THE RÔLE OF THE BLOOD PLATELET.

CONCERNING the source, nature, and function of the blood platelet many theories have been put forward. It has been suggested that it is an entirely independent cell, the function of which is at present almost unknown (Achard, Morawitz, Deetjen, Aynaud, and others); that it is the primordial or embryonal stage of the red corpuscle, a view maintained by Hayem and his followers; or that it is a simple corpuscular element or rudimentary cell—one, however, which plays an important part in the coagulation of the blood, the retraction of the clot, and, as some recent researches seem to show, in the processes concerned with immunity. Again, it may be only a fragmentary protoplasmic residuum of other blood elements, or perhaps a pure artefact which has no existence in the circulating blood. In the course of a thesis[1] published at Rio de Janeiro, Dr. Arnaldo Cavalcanti Marques reviews each of these theories and unhesitatingly rejects the last. After considering the physicochemical properties, physiological functions, and probable source of the platelets, he discusses their relation to various pathological states, including internal parasitic affections, suppuration, protozoal infections, affections of the blood and blood-forming organs, and shock conditions. The following statement on variations in the platelet count due to certain morbid conditions is given as representing conclusions with which most observers would agree, and which are confirmed by Dr. Marques's own work. An excess of platelets is present in the blood (hyperglobulinæmia) in intestinal verminoses, suppurations, recovery from loss of blood (after a certain lapse of time from the loss), convalescence from acute illnesses, and in the course of chronic disease. The reverse condition (hypoglobulinæmia) is found in the acute stage of hæmorrhagic purpura, in pernicious anæmia, and in the active period of enteric fever. Dr. Marques considers, however, that globulinometry, or platelet counting, is at present of little value in diagnosis or prognosis. None of the methods used for the count (Hayem, Aynaud, Fusari, Giudiceandrea) are free from the liability to serious error, though those of Hayem and Aynaud, singly or combined, furnish approximate results accurate enough for clinical use. He is convinced that the blood platelet plays a very important part in therapeutics.

NEW YORK ACADEMY OF MEDICINE.

THE Academy of Medicine, which is about to move into a new building in Fifth Avenue, was founded in 1846. Since that time it has fulfilled its original objects by holding regular meetings, by maintaining a large library, and by interesting itself in public health problems. At first the Academy was homeless and used for its gatherings the premises of other medical institutions, but in 1875 it bought a house of its own, and in 1890 moved into its present quarters. It has now 12 sections which meet for discussions or to hear papers by distinguished visitors, and its increasing membership and activities long ago made it evident that the present buildings were inadequate. The library, which is the only public medical library in New York and contains over 140,000 books, cannot expand as it should, and its reorganisation has had to be deferred until new premises are found. This state of affairs attracted the attention of the Carnegie Corporation and the Rockefeller Foundation. They appreciated the potentialities of the Academy as an educational centre and decided to devote large sums to its development. About £300,000 has been given by the Carnegie Corporation for building purposes, and the Rockefeller Foundation has contributed towards the endowment fund of £500,000. These gifts are conditional, however, on an expansion of activities on rather new lines. A full-time director of the Academy's work has been appointed; the library service is to be developed, and a bureau of clinical information under the direction of a committee on public education is to be set up. Public health work at the Academy has hitherto been in charge of a committee which has made important studies in communicable diseases, quarantine, hospitals, dispensaries, day nurseries, convalescent homes, and the problems of chronic disease. That this side of the Academy's work will not be neglected is evident from the appointment as first director of Dr. Linsey R. Williams, who was Deputy Commissioner of Health for the State of New York, and for three years was at the head of the Rockefeller Commission on Tuberculosis in France. Associated with him in the reorganisation and management of the Academy will be Colonel Frederick P. Reynolds, M.D., the head of the Committee on Public Health, and Dr. E. H. Lewinski Corwin who has for some time been connected with the library. From the British point of view one of the most interesting features of the reorganisation is the proposed clinical information bureau, which is to publish a monthly bulletin. In travelling to or from Europe, American and foreign doctors generally pass through New York, and the bureau is to be a clearing house of information on every kind of medical study available in the States, and also on the facilities existing in Europe. New York itself, with its huge foreign population, is a big field for study and research, and it is felt that by coördination and information this field can be made to yield a far larger harvest. The Academy intends to supply efficient machinery.

IODINE AND ENDEMIC GOITRE.

THE successful results obtained in different parts of the world in the treatment of endemic goitre by means of iodine are known, but the ætiology of the disease is not completely cleared up, and it seems to be going too far, as some authors have done, to say that a geographical deficiency of iodine in the air, food, or water is the specific cause of endemic goitre. The more information which can be obtained from different situations as to the distribution of this disease and the relation between this and iodine deficiency, the easier it will become to prove or disprove such a sweeping statement. Prof. D. B. Blacklock has now reported his observations on the occurrence of endemic goitre in Sierra Leone.[1] He endeavoured to put to the test the theory of a geographical distribution in relation to goitre by tracing the Bagwe river up to its sources in the mountains. Goitre occurs endemically over the area drained by this river, and it was expected that since a natural deficiency in iodine in the soil and water would probably be greater at higher levels, a definite increase in the incidence of goitre would be found in these upper regions. The whole expedition occupied three months and had to be done on foot, and so frequently was a village hut the only accommodation at the various stopping places that there was ample opportunity for observing the sanitary conditions of the population at close quarters. The total number of cases examined for goitre amounted to 2405, which included inhabitants of 37 villages. The incidence of goitre amounted to 10 per cent. among the males and 23 per cent. among the females examined. From the geographical point of view the results were interesting. At lower levels along the course of the river goitre was found to be prevalent, while it was absent at the highest villages; but the whole distribution was so irregular that it became necessary to search for some other factor in its causation. It was discovered that in certain villages pollution of the water by excreta occurred to a much higher degree than in others, and this marked pollution was associated with the highest goitre rates. Prof. Blacklock points out that mere deficiency of iodine in an otherwise unimpeachable water-supply does, no doubt, account for the occurrence of endemic goitre in certain areas, as in many parts of America, but at the same time he emphasises the fact that such iodine deficiency may, in other countries, be artificially produced by contamination. He suggests that the fæces which pollute the water-supply in the district he was investigating may fix or deviate the iodine in some way, or, alternatively, that "fæcal substances or substances formed from fæces by bacteria in the water before ingestion are absorbed and alter the metabolism in such a way as to increase the iodine requirement," thus producing a relative deficiency of this element. As Sir George Newman said in his recent survey of public health, the question of causation is at least a two-sided one, deficiency of iodine intake on the one hand and an abnormal condition preventing its proper assimilation on the other.

Although these and similar hypotheses have been suggested by many workers, it must be borne in mind there is little experimental proof to base conclusions upon. It has been shown that inorganic iodine is readily absorbed into the circulation, and is stored in the thyroid, mainly in the form of organic iodine compounds. However attractive these theories may be, they must be regarded with suspicion until definite chemical and experimental evidence is adduced to support them. It is important that a careful study of all suspected waters with a regard to their iodine content be made before any conclusions can be reached on this question. This has already been extensively investigated in America, but it also requires to be done in regions where the pollution factor is more prevalent. Dolbey and Omar have shown[2] that in certain of the Nile villages where pollution is present to a marked degree goitre is prevalent, although the iodine content of Nile water is higher than that of the metropolitan water-supply of London. It would appear that in Sierra Leone also the prevention of endemic goitre is more closely bound up with sanitation than with the administration of iodine.

The investigation of the distribution of endemic goitre in America is gradually being extended to cover most of the country, and a report[3] has been published on the occurrence of this disease in Colorado. Various surveys have been made from time to time in this State in approximately 57 localities, and on the whole the prevalence of goitre appeared to be greater in the western part of the State, where drinking water is obtained from mountain streams and not from wells as in the eastern districts. No information as to the iodine content of the different waters is, however, available, and in the report it is stated that "it is problematical whether the source of the drinking water has any considerable bearing upon the occurrence of endemic goitre in Colorado, except in so far as the water may be deficient in iodine." The combined results of four different surveys in Colorado, in which nearly 4000 boys and over 13,000 girls were examined, showed that 25·6 per cent. of the boys and 30·1 per cent. of the girls had some degree of thyroid enlargement. These results show a much smaller difference between the prevalence rates for boys and girls than in other parts of the country. For the moment the usual methods of iodine prophylaxis and treatment are to be instituted, but a more intensive survey of the State is suggested to discover the nature of the iodine deficiencies in different localities and their relation to the prevalence of goitre. All such information is of the greatest importance if the problem of the ætiology of endemic goitre is to be solved in as satisfactory a manner as the problem of its prevention appears to have been.

A SCHEME OF MIDDLE-CLASS INSURANCE.

A scheme of insurance has just been proposed which is likely to reduce the anxieties of illness for the middle-class family. There is no need again to point out that there is a most important class of the community which has in sickness neither the support of riches nor of the State. It is sufficiently obvious. Practically all the contributory hospital schemes restrict their benefits to those of fairly small income, and as the costs of more complicated medical methods grow larger they form an increasingly formidable sword of Damocles which in suspension whitens the hair and in falling may wreck the home. To insure each member of a family singly against the possibility of disease, in such a way as to cover all medical fees and nursing, is practically impossible for the average man with a small income. Moreover, although a person insured for £6 per week—at a premium of perhaps £6 per annum—may be entitled to claim £30 for disablement by an illness requiring operative treatment, the expense of the operation itself may be as much as £100–£200. The Family Medical Services, Ltd., has issued at Manchester a scheme intended to appeal to middle-class householders who have felt this difficulty. The proposers have the support and advice of Sir William Milligan, and the Association itself has no interest financially in the results of the insurance, which is necessarily speculative in an untried field like this. The policies are underwritten at Lloyd's, so that the security is unimpeachable, and, in contrast to those of some mutual associations which pay benefit only if funds permit, the policies of the Family Medical Services will be definite contracts. Two schemes are issued, the first of which covers only general practitioners' fees, and the second covers, in addition, specialists' fees and operation expenses. It is an essential feature of the scheme that the interests of the underwriters and the insured should be identical, so that the first few pounds paid out in fees, and one-fifth of the operation costs, are borne by the latter. All members of a family residing at home who are eligible must be offered for insurance, and the premiums charged vary, of course, with the number in the family and with the scale of fees and operation charges insured against. No insurance is accepted at any age over 50 at entry, and no child is included of less than 2 years old. At other ages below 12 and above 40 the premiums are larger, and there are certain excepted illnesses including those not common to both sexes; but these are merely the reservations. The benefits are undoubted. The rates charged mean that the average man can secure the services of his own general practitioner, subject to certain conditions, at from 3½*d.* to 9½*d.* a week per member of his family, and can cover four-fifths of the expenses of possible operations for a further 3*d.* to 9*d.* a week. The cost of the minor yet expensive surgery which corrects smaller defects in children, and is not so much vital as advisable, will also be defrayed under this scheme, and this will probably cause the householder to look less gloomily on such interference. The issue of such policies, indeed, seems calculated to lighten a real burden. No medical examination is required, and it is only to be hoped that the terms are not so generous that they will have to be modified.

PRESERVATIVES IN FOODS.

The opponents of the new Ministry of Health Regulations, prohibiting the use of all preservatives except two specified chemicals under rigidly defined conditions, are still dissatisfied and are not only carrying out an active campaign in some of our daily papers, but are proposing to take up the question in Parliament and endeavour to obtain a modification of these regulations. In particular, persistent efforts are being made to represent the boron group of preservatives as both harmless and necessary—like the domestic cat. The subject is of great practical importance, so we make no apology for returning to it and considering the grounds upon which it is suggested the regulations should be modified. These seem to be three in number: that there is inadequate evidence that the boron preservatives are prejudicial; that their elimination will send up the price of many foods in which they are now used; and that their suppression will cause a great increase in "food poisoning."

As regards the harmfulness of boric acid and its salts, there is a respectable body of evidence that when they are present in considerable quantity harm may result from their consumption, and the Departmental Committee on the Use of Preservatives, after carefully considering the evidence, came to a definite opinion on the subject. It is really beside the point to assert that the small quantities necessary for preservation have not been shown to be harmful, since experience has shown that these limits are not maintained, and when the salts are widely used they may be consumed almost daily in a number of articles, thus giving a considerable dose of a substance which is comparatively slowly excreted. The real point at issue, however, is that the use of preservatives is a substitute for cleanliness, and that their addition allows food to be collected, prepared, or stored under conditions which are prejudicial to health. The methods used are only practicable because the added preservative prevents the food decomposing, as it otherwise would under these unhygienic conditions. Their immediate suppression would no doubt dislocate trade and so cause a temporary rise in prices, but this point has not been overlooked in the regulations, which do not come into force immediately, not, in fact, until 1927. Scientific investigators are unanimous that cold storage is a preservative greatly superior to added chemicals and that it can with advantage to public health replace them. There is no trustworthy evidence that such a change will cause a general increase in cost, although certain special types of food may be affected.

The suggestion that the suppression of preservatives will cause an increase of food poisoning is hard to understand, for there does not appear to be a single argument to support it. Presumably the idea is that without preservatives more food will be eaten in a tainted condition, since there will be so much more food of this character thrown upon the market. The use of cleanliness and cold storage instead of chemical additions will probably diminish the quantity of food showing early decomposition changes, since the general effect will be a much higher standard of purity. This view shows a singular lack of appreciation of the cause of food poisoning, which has nothing whatever to do with tainted food, but is a definite infection of the food with specific bacilli belonging to the Salmonella and other groups. There is no evidence that boric acid or other chemical preservative has a selective action on these bacilli and will prevent this development, except in so far as their general action is antiseptic. On the other hand, the prevailing factor in the causation of these outbreaks is a defective standard of cleanliness and care of the food which has allowed the specific bacilli to gain access to it and contaminate it. A heightened standard of cleanliness is one of our most important preventive measures.

The Royal Society of Medicine will hold its first social evening of the session at 1, Wimpole-street, London, W. 1, on Tuesday, Oct. 27th.

Malton: A Hospital for 66 Parishes.—For the last 20 years the little town of Malton, in the North Riding, has possessed an inadequate cottage hospital housed in a converted private residence. A new building is now about to be erected upon an elevated site given by Earl Fitzwilliam, with larger accommodation and better facilities for dealing with the cases that come in from the 66 parishes in the district of which Malton is the centre, many of which at present have to be sent to Leeds. The new Malton, Norton and District Cottage Hospital will have a large operating theatre with the necessary annexes and an X ray room.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXIX.—THE SURGICAL TREATMENT OF EXOPHTHALMIC GOITRE.

PART I.—THE DECISION TO OPERATE.

IN dealing with a patient suffering from exophthalmic goitre or other form of hyperthyroidism, the practitioner will always have in mind the general plan of treatment set forth by Prof. G. R. Murray in this series in THE LANCET of August 11th, 1923, and by Sir Hector Mackenzie[1] and Sir William Hale-White.[2] Elimination of septic foci, rest, diet, drugs, X ray and radium treatment, each has its appropriate place, and in the majority of cases does the patient some good. For those patients who respond well to these measures the question of surgical treatment does not occur. Various reasons may, however, be present to cause the question of operation to be raised, and Prof. Murray has indicated them shortly in his concluding paragraph (p. 293).

A discussion of these reasons and of the methods by which the desired result may be achieved with the minimum risk to the patient will form the subject of this article. It is to be understood that the procedures indicated are only to be entertained when therapeutic measures have not been successful; or when, for other reasons, it is deemed inadvisable to delay.

At what Stage to Operate.

At what stage of the disease, then, should operation be performed? The chief consideration will be the fact that the patient is not improving—or is actually losing ground—at the end of a period of treatment, the length of which must vary according to the social position or the family responsibilities of the individual. No actual time limit can be laid down, though it is certain that operation is very rarely called for within the first six months of the disease. There is, however, a limit to the time during which a heart can endure the constant toxicity without failing in some respect, and when the failure begins it is usually progressive; also exophthalmos may become so extreme that its ultimate disappearance is unlikely, or it may lead to corneal ulceration; or, again, the restlessness associated with the disease may appear to be progressing towards mental instability. If conditions such as these are present when a patient first comes under the care of a practitioner, it is a matter for consideration whether there should be any delay in operating except such as is necessary for thorough investigation. Mental instability may even indicate that the time for operation has passed. If the surgeon can coöperate with a physician interested in these cases, some degree of heart failure should not be a bar to surgical intervention, for there is the certainty of great amelioration in the condition of the patient. The occurrence of corneal ulceration, due to extreme proptosis, should determine early surgical intervention, surgeon and ophthalmologist working intimately together.

The social position and family responsibilities of a patient will greatly influence a practitioner. When complications such as those indicated above threaten or are present, surgical treatment becomes imperative whatever the social position of the patient, but if the individual can afford to, and will, rest completely, there is less risk of visceral degeneration than in one who must work for a living or support a family. The time for operating on these patients can be chosen when they become weary of ill-health, or when the practitioner realises that enough time has been given to non-surgical treatment. With the poor patient the case is different. Even here operation should not be unduly hurried, but women earning their own living and working-class mothers or fathers of families can rarely rest at home, and there are not enough hospital beds available to give all of these patients continuous rest and nursing for a sufficiently long period. It is to be remembered that it is usually a matter of years and not of months. Furthermore, it is a fact that, because of this lack of facilities for rest, these patients lose ground more quickly, drift around from one out-patient department to another, with occasional periods of rest in hospital, and are not only unable to support themselves or their families, but become permanently ill. The economic factor, therefore, determines surgical treatment earlier in the less well-to-do classes of the community. A review of these factors will, in most cases, leave no doubt in a practitioner's mind when, in the patient's interest, the time has come to consider surgical intervention.

Special Operation Risks.

Such patients present some special operative risks not present in the average surgical case. The symptoms of the disease become incompatible with life if they are allowed to increase beyond a certain degree. Operation undoubtedly augments all of these, at least, temporarily. The knowledge that operation is impending, and the preparation for it, stimulate the activity of the gland, apart from the actual handling of it during operation. This cause was recently responsible for the sudden death of a young patient in the throat department of a hospital while she was waiting for her tonsils to be removed. Extreme mental unrest is a dangerous symptom. Glycosuria is not infrequently present and its type must be determined. If it can be, and is, controlled, it is not a contra-indication to operation, but if it cannot be checked operation should only be performed after careful weighing of the factors. No operation should be performed while the slightest catarrhal condition of the respiratory system is present, because the handling of the region of the laryngeal nerves and the trachea stimulates secretion and interferes with its efficient expulsion, and if catarrh has been present before operation much inconvenience and some danger result. A high basal metabolic rate, and a pulse-rate persisting at or above 130 per minute while a patient is in bed would indicate that operation should be postponed. These conditions can often be controlled temporarily, but sufficiently, to render operation safe (vide infra). Walton[3] has drawn attention to a fact recognised by all concerned—viz., that patients are decidedly more unhappy in warm weather. This is due to the fact that the skin is always hot and moist, and so heat cannot be eliminated rapidly enough for comfort or safety. Therefore no operation should be performed during a hot spell. C. Mayo has pointed out that it is not an emergency operation, and patients should always await the most suitable time. Lastly, loss of cardiac compensation brings its own dangers, and patients in this condition should only be handled surgically in coöperation with a physician who is accustomed to deal with this type of case, and whose judgment can be relied upon to determine what can and what cannot be done.

Preparation for Operation.

In spite of the general agreement that operation is only to be considered after efficient medical treatment has been carried out, it is essential—in the light of constant personal experience—to re-state the imperative necessity of attention to teeth and tonsils before operation. The frequency with which patients come for operation with large septic tonsils or septic teeth still present shows that the importance of buccal hygiene is not yet sufficiently appreciated by practitioners as being one of the chief factors in medical treatment.

A patient should be prepared to spend at least seven or ten days in bed before operation. During the first two days the pulse-rate is recorded while the patient is kept at complete rest, but without medication. This shows the drop that occurs as the result of rest and freedom from outside worries. Physical examination, measurement of basal metabolic rate, and urinalysis are carried out. Then iodine medication is given (Plummer,[4] Mellanby,[5] Fraser[6]), Lugol's solution, ♏ x., once a day being sufficient; often too much is given. The resulting drop in the pulse-rate and in the basal metabolic rate is definite, and reaches its maximum in about a week, and the excitability of the patient is usually decreased. The vascularity of the gland and the danger of operation are also reduced, so that the operative death-rate has been brought down from about 4 per cent. to nearer 1 per cent. in the hands of surgeons accustomed to operate upon cases of average severity. This does not mean that a severe case of Graves's disease, or an ordinary case which has undergone an exacerbation of the condition, may be given iodine treatment for a week and then operated upon with impunity; but it is a fact that some patients, who have not responded to rest and the drugs commonly used, do improve in a remarkable manner with small doses of iodine, and have been rendered fit for operation. Iodine must not be given unless the patient is in bed. Larger doses do harm, and no good purpose is served by continued administration. During these ten days of preparation the surgeon is gaining the confidence of his patient.

Special Articles.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 620.)

VIEWS OF TRADE-UNIONS.

(App. XCII. and Q. 21828–22183.)

EVIDENCE was submitted on behalf of the National Association of Trade Union Approved Societies by Mr. F. Kershaw, Mr. E. Corbey, Mr. G. W. Canter, and Mr. G. P. Blizard.

This Association has an aggregate membership of 1,162,130 insured persons. With regard to the working of the Approved Society system it was stated that 12 years' administration of the Act has led to the conclusion that the "fraternal" factor is a diminishing quantity where it does exist, and that it does not exist at all in the case of vast numbers of insured persons. Further—

> Under the present system the "unhealthy" society cannot provide additional benefits, while the "healthy" society can be made still more healthy by the treatment benefits provided through its surplus, which in their turn will produce still greater surpluses in future years.

As to medical benefit, the view of the Association is that while the panel doctors have, as a whole, rendered competent and conscientious service, the limitation of the range of service constitutes a grave defect, and that—

> The term "medical benefit" should mean everything that medical and surgical science can command for the prevention or cure of sickness, or, in terms of the individual, everything which the medical profession considers necessary in order to restore a sick person to health.

Medical benefit should also be extended to wives and dependants and the cost of the enlarged service met by contributions, as at present, and by grants from the local authorities, and also by economies to be effected through coördination.

If a valuable medical service were provided, the Trade Union Approved Societies were not afraid to go to their members for essential contributions.

> (Q. 22048.) *Do you think that under the present conditions of unemployment and depression in industry, and having regard to the new contributions and grant charges proposed under the Widows, Orphans and Old Age Pensions Bill, an increase in the charges for the Health Insurance Scheme is justifiable?*—We note that the question, before it was amended to incorporate pensions, has been put to many previous witnesses. Our reply at the time our evidence was decided upon would have been: Give us value for money and we are not afraid of the decision of our members.

It was not unreasonable to assume that if the trade-unions had recommended an increase of 8*d.* in the contributions—the amount of the new charge for pensions insurance—they would have been considered extravagant dreamers. While not recommending the abolition of Approved Societies, mainly because such an attempted step would give rise to insuperable political difficulties, the witnesses recommended that they should be confined to cash services only.

With regard to a whole-time salaried medical service the witnesses said that this was no essential part of their scheme, but they submitted that the history and traditions of the medical profession showed that it stands out as one in which devotion to duty, to science, and to public welfare takes first place, and they could not agree that medical men would change their characters "if they became public servants instead of the servants of the public."

All hospitals, it was contended, should be organised under one public authority with allied treatment centres. The Labour Party would give voluntary hospitals the option of being taken over by the health authorities entirely or of receiving grants from public funds conditional on efficiency. Pressure on hospital beds in the towns should be relieved by the transfer of convalescent cases to country homes.

EVIDENCE OF APPROVED SOCIETIES.

Grand United Order of Oddfellows (App. XCV. and Q. 22405–22597).—This evidence, which was given by Mr. W. McLean, accountant to this Society, was mainly on questions of machinery as affecting Approved Societies, and included a recommendation that dental treatment should be provided as a general statutory benefit to be administered by the Approved Societies, and a suggestion that the Minister's Consultative Council should be reconstituted on a more representative basis.

United Patriots' National Benefit Society and International Society of Medical Hydrology (App. XCVI. and Q. 22598–22730).—The evidence given jointly by these bodies was confined to the question of spa treatment, and was submitted by Mr. J. M. Roberts, Dr. Fortescue Fox, and Mr. John Halton. The Approved Society has been impressed by the large proportion of its own sickness claims due to rheumatism and allied disorders. They also quoted the Ministry of Health's report, as follows:—

> Nearly one-sixth of the industrial invalidity of this country is due to diseases classified as "rheumatic." Each year these diseases are costing Approved Societies nearly £2,000,000 in sick benefit, and the nation over 3,000,000 weeks of work from the insured population alone.

The importance of spa treatment was urged upon the Commission, and it was stated that the spas forming the British Spa Federation were prepared to put into operation a scheme for the treatment of insured persons. It was suggested that while such a scheme at the outset would require financial assistance from the Treasury, its cost would be reflected in large economies in sickness benefit. The suggested scheme included the certification for spa treatment by the panel doctors, examination by a small medical board at each spa, and the extension of existing accommodation by the establishment of hostels or approved lodgings.

[5] Mellanby, E., and Cowell, S. J.: Quart. Jour. Med., 1924, No. 69, p. 1.

[6] Fraser, Prof. F. R.: Brit. Med. Jour., 1925, i., 1.

* References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

The witnesses appeared fairly confident as to the practicability of increasing the spa accommodation and the availability of the supply of waters, so as to afford adequate treatment to those of the insured population suffering from rheumatic diseases. It was thought that three-tenths of such cases were suitable for spa treatment.

Scottish Coöperative Friendly Society (App. LXXVIII. and Q. 20116–20341).—Mr. W. Thomson, secretary of this Society, gave evidence which included proposals that medical benefit should be extended to the dependants of the insured, and that sickness benefit should be raised at least to the level of unemployment benefit.

The advisability of increasing maternity benefit is doubtful unless steps were taken to limit the fee charged by doctors for attendance at confinements. In practice we understand this benefit is almost or wholly absorbed by the doctors.

Dental benefit, it was submitted, should be extended and made statutory; judging from inquiries received, optical benefit was thought to come next in popularity. It was suggested that where, on questions of medical certification, the State medical referee differed from the panel doctor, the difference, instead of being referred to arbitration, should be settled by the Board of Health bringing the parties concerned together, hearing the evidence, and deciding the matter as between the medical experts and the insured person.

(Q. 20269–70.) Would not that need a third medical man if you want an expert interpretation of the medical certificates?—I would have hopes that the two medical men, the State referee and the panel doctor, if brought together, would come to agreement.

One would have to admit he was wrong?—Yes, and one has to admit he is wrong under present circumstances.

Edinburgh Friendly Societies' Council (App. LXXXI. and Q. 20637–20759).—Mr. T. J. Addly gave evidence. This Council, representing 100,000 insured persons in Edinburgh and district, was opposed at present to the extension of the insured class, but thought that the benefits under the Act should be extended so as to include nursing, dental treatment, and the services of specialists and consultants. They were of opinion that the present method of administration by Approved Societies and Insurance Committees should be continued.

Nursing was regarded as the first essential extension, although the witness agreed that the services of specialists and consultants, as the natural complement of medical benefit, should logically come first. The Council, however, felt that these services could wait as part of an insurance scheme, because of the extent to which they were already available free to insured patients at hospitals.

Sons of Temperance (App. LXXXIX. and Q. 21305–21631).—The membership of this Society is 131,000. Evidence was given by Mr. T. W. Huntley. Recommendations with regard to specialist and consultant services included a suggestion that, in the first instance, there should be a freer and fuller use of the known abilities of those panel practitioners with exceptional qualifications. As the Regional Medical Staff of the Ministry were empowered to employ specialists in exceptional cases, it was thought that this provision might serve as the basis on which to build up such a service. Dental benefit, as a statutory benefit, was the subject of a somewhat qualified recommendation.

As regards the millions in the reserves of Approved Societies, it was stated that there was much misconception in many quarters.

As regards surpluses, similar misleading and exaggerated statements have been made. It seems to be overlooked that there are 11,000,000 or so of insured persons, and that even at the 1922 and 1923 valuations the average surplus declared as available for disposal is, roundly, £2 per insured person, and this sum is to be spread over five years.

---

Evidence of the British Hospitals Association, the Sheffield Joint Hospitals Council, and the Middlesex Hospital (July 25th, pp. 181–2); Evidence of Opticians' Associations (August 1st, pp. 224–6); Evidence of Council of British Ophthalmologists, of Ophthalmic Benefit Committee, of Chemists, and of Drug Store Proprietors (August 15th, pp. 348–50); Evidence of Chartered Society of Massage and Medical Gymnastics, of the Ivory Cross, of Scottish Panel Chemists, Practice among Highland Crofters, and of National Farmers' Union of Scotland (August 22nd, pp. 402–3); Evidence of Nursing and other Women's Organisations (Sept. 5th, pp. 519–20).

WOMEN'S MEDICAL SERVICE FOR INDIA.

THIS service is open to fully qualified medical women of British or Indian nationality who desire to carry on work in India. With the present amount of Government subsidy the number of medical officers is limited to 44. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals. Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service. To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare; medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions.

Rates of pay are as follows:—

Years of service.	Overseas allowance per mensem.	Salary per mensem.	English equivalent* per annum.
1 to 3	Rs.100	Rs.450	£440
4 to 6	"	Rs.500	£480
7 to 9	"	Rs.550	£520
10 to 12	"	Rs.600	£560
13 to 15	Rs.150	Rs.650	£600
16 to 18	"	Rs.700	£640
19 to 21	"	Rs.750	£680
22 to 24	"	Rs.800	£720
over 24	"	Rs.850	£760

* At rupee value 1s. 4d.

Furnished quarters are provided, representing an additional Rs.150 per mensem.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.200 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills.

One month's privilege leave on full pay is granted each year. Furlough on half-pay at the rate of two months for every year of service is granted after every three years. Study-leave on two-thirds pay is granted to the extent of 12 months in the total service. There is a provident fund to which members of the service contribute 10 per cent. of their pay. The service contributes another 10 per cent. which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection. Candidates in the United Kingdom should apply to the Hon. Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of Major-General J. B. Smith, India Office, Whitehall, London.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Criminal Abortion in Germany.

THE problem of the increasing number of cases of criminal abortion was discussed at the annual meeting of the Association of Bavarian Medical Men recently held in Augsburg, where Dr. Hoeber read a paper on the subject. He stated that the birth-rate had decreased from 27·6 per 1000 in 1903 to 20·4 per 1000 in 1924. In 1906 two million living children were born as compared with 1,300,000 in 1924. While the decline of the birth-rate might be partly due to venereal diseases and to contraceptive practices, he attributed a large proportion of it to abortion. Dr. Hirsch, of Berlin, stated that the relation between miscarriages and normal births in the capital was 93 to 100, and Dr. Hansberg, of Dortmund, found that in Germany about 1,000,000 abortions took place annually, with a mortality of 6000. In Bavaria alone, in 530 cases of puerperal fever occurring after a normal birth the mortality was 104, while in 113 cases of puerperal fever occurring after an abortion there were 54 deaths, being a mortality of nearly 50 per cent. This record shows how much more liable to puerperal fever women are after abortion than after normal childbirth. The number of convictions for criminal abortions in Bavaria was, in 1916, 72; in 1918, 138; in 1919, 119; in 1920, 293; in 1921, 538; in 1922, 660; in 1923, 586; in 1924, 690. It is notable that abortions are less frequent in unmarried than in married women, especially where there are already children in the family and the parents feel unable on economic grounds to cope with more. In Germany the excess of births over deaths was 12·1 per 1000 in 1913 against 7·1 per 1000 in 1924. It has been proposed not to punish artificial abortion when performed for economic reasons, so that it might be performed by respectable medical men instead of by unqualified and disreputable persons or midwives. In this way a good many women might be saved from puerperal fever. Dr. Hoeber rejected that proposal and the Association endorsed his view. According to him, it would be a mistake to abolish or to reduce the penalties for criminal abortion without a reduction of penalties in general. It should be the duty of the State, he said, to help poor parents in bringing up their children by providing dispensaries, creches, free meals, and such like. Foundling institutions after the pattern of those existing in some southern countries were not recommended. The children brought up in those institutions without a home and without maternal care, he held, did not prosper. Illegitimate children should, as far as possible, have the same rights as egitimate offspring.

Diseases in the Navy.

Dr. Ruge, a naval surgeon, gave a historical survey in a recent issue of the *Marine-Rundschau* (Naval Review) of some morbid conditions which might be considered endemic in the navy. He first stated that drunkenness was gradually decreasing. Whilst in the "seventies" 0·28 per 1000 of the crew suffered from chronic alcoholism, that number had dropped to 0·08 per 1000 in the period of 1910–14 and had decreased still further during the war and after. Diseases due to acute drunkenness had decreased from 0·52 per 1000 in 1874 to 0·17 per 1000 in 1914. The diseases which he considers to be particularly prevalent in the navy are: colds, injuries, cellulitis, furuncles, and venereal diseases. Colds had been very frequent, the number being, in 1878, 940 per 1000, so that nearly every man had been infected during a year. The number had decreased to 490 in 1912, whilst after the war it had risen again to 570. Diseases connected with colds were tonsillitis, laryngitis, pharyngitis, pneumonia and pleurisy, rheumatism of muscles and joints. Engineers and stokers were especially liable to colds owing to the rapid change between hot and cold air to which they are exposed. In 1896, when wooden ships were still in commission, it was stated that the ratio of cases in such ships, as compared to iron ships, was as 3 is to 4. Among sailors the number of cases is lower than among stokers and engineers, while in the army the case-incidence is three times smaller than in the navy. An improvement had been obtained by compelling the men to change their wet clothes and to keep hardened by going bare foot and by providing cold baths and douches. According to statistical records, injuries are most frequent on Mondays and then decrease throughout the week, a fact in accordance with observations made by the Workmen's Insurance Offices, with regard to artisans being obviously in connexion with the relaxation occurring after the Sunday's pleasures. Formerly injuries were still more frequent and were particularly severe too in the heyday of sailing ships; one-third of the crews suffered from injuries, whilst now only 5 per cent. were affected. As to furunculi, the report states that those on the neck are very rare owing to the absence of collars in the navy, but it is striking that sailors suffer more than stokers, so that possibly the coal-dust may have a disinfectant action. Venereal diseases were a curse to the navy in foreign ports; in the former East Asia Squadron one-third of the men on an average suffered from venereal diseases. In the whole navy for the past year 17·4 per 1000 were syphilitic, as against 11·8 in 1913. After the war the number of syphilitic patients rose to 34·6 per 1000; this rate, however, was less than that of the merchant marine. Although no exact statistical records exist for the merchant marine, the officer of health of the port of Hamburg discovered 7000 cases of venereal diseases among the sailors within one year. Neurasthenia is not uncommon in the navy as a result of the severe duties, the influence of spirits, and of the climate of the tropics; it was almost unknown in 1877, where only 0·45 per 1000 were recorded, against 5·4 in 1923. Of tropical diseases, dysentery and yellow fever already before the war had nearly disappeared, while malaria had decreased from 78·1 per 1000 in 1877 to the insignificant incidence of 0·07 per 1000 in 1923.

Deaths from Electric Currents.

According to a report made by Dr. Alwensleben to the Berlin Medical Society about 300 deaths annually occur in Germany from electric currents. In Berlin alone 600 injuries are recorded of which ten on an average are fatal. Death from electrical currents cannot be confirmed by post-mortem examination, as the danger of electricity is dependent on the intensity of the current and the duration of its action. Experiments on animals showed that a current of 20 volts did not produce any symptoms, but that 120 volts caused fibrillation of the heart, leading to death, although occasionally the cardiac action could be restored. 2100 volts produced an immediate cessation of respiration, death occurring in one-fifth of a second. Currents of high tension produce severe burns. Two injured persons were shown to the society where currents of 15,000 volts had produced destruction by burning of an arm which was subsequently removed by operation. The direction of the current is, of course, essential for the prognosis. People with a so-called thymic constitution run greater dangers than others. Artificial respiration may sometimes save life, but the application of faradic currents to the vagus nerve is not advisable.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Irish Free State and the Medical Register.

As anticipated last week the controversy regarding the Medical Register has entered on a new and more encouraging phase. The meeting of medical practitioners, summoned to protest against the proposed action of the Government, contented itself with a less intransigent attitude. The principal resolution was one welcoming President Cosgrave's invitation to a fresh conference, and expressing the hope that the conference might lead to a solution of the problem. On the following day the Consultative Subcommittee met Mr. Cosgrave, together with Mr. McGilligan, Minister of Commerce, in a long conference. In a carefully worded communiqué subsequently issued it is stated that:—

> "At the conclusion of the proceedings it was understood that very considerable agreement on a line of policy had been arrived at consistent with the Government's decision to set up a separate Register and Council. It was generally felt that arrangements could be made to maintain existing rights and advantages of Irish practitioners qualifying in the Free State wishing to practise in England and elsewhere. It was also understood that the teaching schools would be in a position to assure their students that no hiatus would arise between the cessation of registration as at present and the adoption of a new scheme."

It is understood that the Free State Government is in hope of obtaining the consent of the British Government to a full measure of reciprocity between the Registers of the two countries. If they are successful in this then the main objections to the Government policy will fall to the ground. It is satisfactory at any rate that the Government and the representatives of the profession are now working in harmony.

Sept. 14th.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.: A. R. Fisher to the *Columbine*, for R.N. Hospl., Queensferry; T. A. Smyth to the *Vivid*, for R.N. Barracks, Devonport; W. G. Edwards to the *Barham*, and as Squadron Medical Officer; and R. F. MacMahon to the *Malaya*.

Surg. Lt.-Comdrs.: F. E. Fitzmaurice to the *Vindictive*, and W. G. Thwaytes to the *Excellent*, both as specialists in Ophthalmology; F. G. Hunt to the *Champion*; and J. S. Elliot to the *Mackay*.

Surg. Lts.: W. G. F. Murray to the *Scarab*, and J. G. Maguire to the *Barham*.

ROYAL NAVAL VOLUNTEER RESERVE.

L. B. Hartley to be Surg.-Lt.

ROYAL ARMY MEDICAL CORPS.

Lt.-Gen. Sir C. H. Burtchaell, ret. pay, late R.A.M.C., is appointed Col. Comdt., vice Maj.-Gen. Sir H. R. Whitehead, ret. pay, late R.A.M.C.

Maj.-Gen. Sir W. G. Macpherson, ret. pay, late R.A.M.C., is appointed Col. Comdt., vice Maj.-Gen. Sir D. Bruce, ret. pay, late R.A.M.C.

SUPPLEMENTARY RESERVE OF OFFICERS.

Capt. N. H. Smith, late Temp. Capt., R.A.M.C., to be Capt.

ROYAL AIR FORCE.

Flying Officer T. V. O'Brien is granted a permanent commission in the rank stated.

The undermentioned are granted short service commissions as Flying Officers for three years on the Active List: J. McM. Wilder and H. G. Maguire.

Flying Officer H. W. D. Mackenzie is transferred to the Reserve, Class D. 1.

INDIA AND THE INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Col. F. O. N. Mell.

Temp. Lt. Shiva Shankar Gupta to be Temp. Capt.

Behari Lal Chopra to be Temp. Lt.

The following have been granted leave: Maj.-Gen. S. F. St. D. Green, Deputy-Director of Medical Services, Western Command. Lt.-Col. A. Leventon, Superintendent, Campbell Medical School, Calcutta. Lt.-Col. A. W. Overbeck-Wright.

The following officers have been posted to Burma: Lt.-Col. E. T. Harris and Majs. S. T. Crump and H. A. H. Robson.

Maj. (actg. Lt.-Col.) (now Lt.-Col.) H. M. H. Melhuish relinquishes the actg. rank of Lt.-Col. on ceasing to comd. a Field Ambulance.

Maj. (actg. Lt.-Col.) (now Lt.-Col.) R. B. B. Foster relinquishes the actg. rank of Lt.-Col.

HOMES AND EMPLOYMENT FOR CONSUMPTIVES.—On Sept. 9th Dr. F. G. Bushnell addressed the Plymouth and District Trade and Labour Council on the need for the proper care of the tuberculous in Plymouth. He asserted that the tuberculosis medical service as it now exists leaves the problems half solved, and is wasteful of both life and money. A system which allows the patient to return to almost certain relapse, and spread of infection to others, is inhuman and unsound. The care and after-care of consumptives should include settlement, housing, and employment, the maintenance of the families of patients who cannot support themselves under ordinary industrial conditions, and their medical supervision. Dr. Bushnell impressed upon his audience of trade-unionists that the principle of employment he advocated is totally opposed to that of exploiting a trade by untrained persons, and that it is quite different from patching up a man so that he can return to his original occupation and infect other men. What must be grasped was that many ex-sanatorium patients can even earn their own living at their own trade, provided that the hours are regulated to their strength, and provided that dividend earnings are reduced or foregone and the large overhead charges taken off their shoulders. But the surroundings must be adapted to their physical and mental condition. To return to the conditions of outside industry usually meant disaster, and after the sanatorium treatment and adaptation to work patients should remain as members of special colonies. Where it was impossible for a person to support himself by his own efforts in such a protected colony, he might still work a reasonable number of hours a day; the balance of loss must be overcome by a subsidy. The only successful tuberculosis settlement was that at Papworth, Cambridgeshire, and amongst the lessons of this great experiment were the following: Patients cannot be trained to a new occupation and left to battle alone with the industrial conditions of commercial life; the wages paid to skilled men must be at the trade-union rate for the number of hours for which they can work without injury; there must be a prospect of promotion in the mind of every settler—e.g., from sanatorium to hut or hostel or cottage, and, in the workshops, from part to full-time employment at union rates and advancement to being head of a department. The products of the settlers must be sold in the open market under the usual conditions, and the medical treatment and supervision must be as efficient as obtains in the best sanatoriums. In conclusion, Dr. Bushnell pleaded for support of a scheme for Plymouth along such lines. Twenty overcrowded badly-housed families, with the (so-called) bread-winner a consumptive, might go into decent healthy wholesome quarters, and at the same time Plymouth would benefit by the reduction of its consumptive population.

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS IN 1925.

WE are requested by the Registrar of the General Medical Council to publish the following list of medical practitioners who have not replied to his inquiries as to the accuracy of their addresses. Anyone who finds his or her name included in this list should communicate immediately with the Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W. 1, otherwise the name will be omitted from the next issue of the Medical Register.

Three County Areas.

Cumberland.—Dr. F. H. Morrison warmly praises the loyalty and support of his staff, medical as well as nursing, in carrying out their ever-increasing duties which have called for many hours of overtime. Depression of trade and unemployment, with their consequent lack of funds, produce more ailments among the children, coincident with lessened ability of the parents to obtain private medical treatment. Dr. A. H. Towers has drawn attention to the prevalent but unnecessary method of marching children into the class-rooms with much stamping of their feet—to keep time with the piano—and so raising clouds of dust which is highly injurious to the whole school population. He suggests that as little noise as possible should be the aim. Many methods for allaying dust are now in use in various places—e.g., the periodical spraying of floors with a dustless oil not only allays the dust, but decreases the cost of scrubbing, and prolongs the life of the treated floor. Dr. Morrison questions why there should be a bigger percentage of intermediates (17 per cent.) and of leavers (15 per cent.) requiring treatment than of entrants (14 per cent.). Is it not largely accounted for by the fact that the vision and hearing of entrants is very seldom tested at routine examination? The main causes of pathologically enlarged tonsils and adenoids are summarised as (1) bad teeth; (2) insanitary conditions of any kind; (3) impure water-supplies. All of these admittedly aggravate the condition, but the cause or causes lie deeper, as is evidenced by the *many* sufferers who have never been subjected to any such disadvantages. Since only one dentist is employed, none but the worst cases of dental caries can be referred to him.

Kent.—Among many interesting tables in Dr. A. Greenwood's report is one showing the percentages of dental caries in the various routine age-groups. The 8-year-old children, as is usually found, have the worst teeth. Mr. C. E. Thomas, one of the dentists, draws attention to the increase of dental caries at all ages. Much *propaganda* work is carried out by the dentists in lectures to mothers both at the schools and at the welfare centres. Dr. S. A. Tucker, in his inquiry on "the health of groups of school-children with special relation to breast-feeding," shows how, in almost every particular, the breast-fed child carries its early advantage well into school life. A smaller percentage of dental caries is present in breast-fed children than in hand-fed. Throat, nose, and ear trouble is less, and the percentage of breast-fed children having "*no history of illness*" is twice that of hand-fed children. Dr. F. Wolverson, in his investigation into malnutrition, finds that bread and margarine with tea is the common breakfast in Kent, and bedtime is "any old time." In a laudable endeavour to stimulate the interest of the parents he runs a voluntary "nutrition" clinic in his own time and without expense to the local authority. Dr. Greenwood remarks on the large amount of malnutrition recorded in secondary schools—378 cases among the girls and 126 among the boys. This is a disquieting feature and deserves the attention which Dr. Greenwood proposes to give to it. Dr. J. Selfe reports on the condition of tonsils and adenoids, for which he recommends treatment—only *local conditions are mentioned, but the local sepsis* may and often does have general ill-effects, and many anæmic and pretuberculous children have reacted extraordinarily well to the radical removal of septic tonsils and adenoids. Dr. W. Lessey finds there is a greater proportion of children showing marked anæmia in the country schools than in the town schools in his area. The macroscopic judging of anæmia is so dependent on the personal factor as to be misleading, and Dr. Lessey's percentages are very high—viz., 21 per cent. (slight and marked) in country schools and 19 7 per cent. in town schools. He associates the anæmia with four conditions: (1) Loss of blood from body parasites, mainly fleas, and from this cause he estimates that in the worst cases of flea bites some children were losing "pints of blood each year." (2) Diet—the iron-containing foodstuffs are largely omitted in the common dietary of these children. (3) Defective teeth. The proportion of dental caries is higher in country children than in town children, largely owing to lack of dental attention. (4) Ventilation and heating. The hygienic home conditions in the country are worse than in the towns.

Nottingham County.—Dr. T. E. Holmes, the school medical officer, contributes an introduction to a report by Dr. C. Tibbits, the senior assistant. The idea of furnishing the names of the 14 clean schools is an excellent one. Dental conditions and treatment are fully described—the quality of the work is evidently better than the quantity, but the reasons for the low percentage of defects treated (34 per cent.) are clearly stated. There is no special school of any kind in the area, except one which deals with mentally defective boys only, and the lack of a mentally defective girls' school is rather serious. For other types of exceptional children it may be said that a fair use appears to be made of special schools and institutions in other areas. There have been some excellent voluntary orthopædic clinics recently established by the Nottingham Cripples Guild, where all kinds of early treatment and after-care are carried on. A special investigation deals with goitre, as suggested by the Board of Education, but on more extended lines. The incidence is compared according to locality, environment, and geological formations, and it is shown that none of these have any marked influence in this county; in fact, limestone formations are actually associated with the lowest figures. The only definite difference is the higher figure for the western districts, and for this Dr. Tibbits discusses a possible explanation—namely, that the western side of the county is more shut off from the sea winds in which some at least of the iodine travels.

Three Urban Areas.

Bilston.—In his short report Dr. T. Ridley Bailey draws attention to the poor hygienic condition of many of the schools in the area. Structural defects are admittedly difficult of remedy in these financially stringent days, but mere lack of attention on the part of school caretakers is reprehensible. Since the S.M.O. is also M.O.H., and carries out his duties unassisted except by one school nurse, the work must of necessity suffer—the small numbers of special cases (13) and of reinspections (14) seem ample evidence of this, and is reflected in the lack of interest of the parents, only 28 5 per cent. being present at routine examinations. No school dentist is employed, and as Dr. Bailey states: "With 43 per cent. of children showing four or more teeth decayed and 37 per cent. with conditions less severe, the committee have abundant evidence that the appointment of a dental surgeon is extremely urgent." No case of bronchitis and only one cardiac (functional) defect is recorded in the return of defects found at medical inspection. Apparently no special provision is made for abnormal children in the area.

Colchester.—The comparative tables given by Dr. W. F. Corfield show at a glance the results of the work during the last few years. The progressive growth of cleanliness and the consequent decrease in "dirt" diseases is clearly shown. The percentage of clean heads has risen from 89·7 per cent. in 1922 to 94·7 per cent. in 1924, while scabies, impetigo, blepharitis, and conjunctivitis have all decreased in the same period. Appreciation of the benefits of the medical work is evidenced among the parents by the percentage who attend the inspections—viz., 77·8 per cent It was thought advisable to close many of the schools during epidemics, but it is extremely doubtful if this measure is at all effective in urban districts. To provide for those children with very defective eyesight a new "sight-saving class" with up-to-date apparatus was established. In spite of further provision being made for dental treatment, 60 per cent. of the children requiring treatment failed to get it.

Coventry.—Dr. E. H. Snell remarks that the increase of verminous heads from 1400 last year to 2200 this is more apparent than real, and is accounted for by the fuller inspection consequent upon the increase of nursing staff. Tuberculosis is comparatively rare amongst the school population, the percentage of definite cases of all forms being only 0·15 per cent., and more than half of these are cases of glandular affection. Visual defects were found in 7·6 per cent. of the children examined, and comment is made on the not uncommon discovery of children of 11 years with very bad eyesight. It is in such cases that observant teachers could render much assistance by bringing them to the notice of the S.M.O. Only 54 cripples of school age are known to the school medical department, and amongst them no case of cardiac defect is mentioned. This is an incredibly small number, as Dr. Snell himself admits. No case of malnutrition was noted during routine medical inspections, and only three cases of anæmia were seen—either the standards adopted by the examining officers are very low or Coventry is an unusually healthy place. Comment is made on the percentage of poor nutrition being highest in the intermediate group, and it is tentatively suggested that this may be due to war conditions falling heaviest on this group. In part it may be so, but the 7 to 8 year old period is essentially the "stretching" period when the children of that age are relatively taller and thinner. Two excellent open-air schools are held, but the accommodation is much too limited for the number requiring such treatment.

PORT SANITARY AUTHORITIES.

THE annual report of the medical officer of health to the port sanitary authority of *Liverpool* for the year 1924, signed by Dr. E. W. Hope, the former M.O.H., and by Dr. A. A. Mussen, his successor, gives a very full account of the discharge of great responsibilities of these officers in relation to the port. As regards infectious disease, only one case of small-pox (from Lisbon) was landed; from *one* ship eight cases of typhoid were recorded (from Bombay), one died on board, three were sent to Fazakerley Hospital, four were later reported from their homes; no cases of plague, cholera, or typhus occurred; 58 cases of phthisis came under notice, 29 in sailors and 29 in passengers. Several infectious cases were accommodated in the port sanitary hospital at New Ferry. Grain dermatitis caused by a mite (*Pediculus ventricosus*) in barley from Morocco occurred among dock labourers, and people living in adjacent houses into which the dust of this cargo was blown were also infected. Rats to the number of 62,953 were caught or destroyed; in the city, 1120 were black and 15,171 brown, but in the port the proportions were reversed, 14,809 being black and 326 brown—in all over 15,000 of each. Five ships were fumigated with hydrocyanic acid, averaging 21 rats killed in each, and in 106 ships sulphur dioxide was used, averaging 60 dead in each. The number killed by the Corporation staff is not a measure of the staff's activity, as its chief function is to keep moving on and taking samples for examination from all round the port in order to get early warning if the rats in any area are becoming plague-infected. Of 6506 rats inspected in 1924 all were free of plague. Rat-catching in ships is the duty of the owners. The number of rats ashore is diminishing by extended use of ratproof sheds. Rats find harbourage in temporary wooden offices, in accumulated sweepings, and in heaps of working gear. One inspector devotes most of his time to this problem; his standard is high, and he has secured the coöperation of the officials of the docks: "some even admit that it pays." An investigation on the destruction of vermin, particularly bedbugs, as carried out by Prof. R. Newstead and others, is reported in an appendix. As a result of the investigation, 3 per cent. hydrocyanic acid gas is recommended for the complete extermination in three hours of bedbugs and their eggs, but tongued and grooved wooden linings of the compartment must first be removed. Venereal diseases are being firmly tackled; there is a seamen's dispensary, with a staff consisting of a whole-time assistant medical officer and two orderlies, one of whom lives on the spot, and is on duty daily till 8.30 P.M. The average patient is very attentive to treatment, but many cease attendance prematurely. Printed cards of advice are issued to ships giving the address of the dispensary, and a small map showing its position. During its ten months of work 428 new cases have attended. The illustrations show the excellence of its equipment. 5194 ship inspections were made by inspectors, 732 by medical officers. Of the nuisances, 91 per cent. were due to lack of cleanliness, often because sailors when they leave ships leave them in a very dirty condition. It is becoming more usual now to take on an extra hand (called a "Peggy") to attend to the cleanliness of the crew spaces, so these dirty conditions may be less constant a feature in future. Many aliens (20,594) arrived in Liverpool during the year; four were rejected as weakminded or insane, two as suffering from communicable disease, one, a case of trachoma, deported from the United States, as "having a disease likely to cause him to become chargeable to the public." British emigrants numbered 86,693, more than half going to British North America; of the second and third-class passengers, who are all examined by Board of Trade inspectors, 18 were rejected as having infectious disease. Second and third-class passengers for the United States are inspected by a medical officer of the U.S. Public Health Service; if verminous they are disinfested, along with their baggage, at one of the city hospitals. There are seven trained food inspectors, so little delay is caused in the inspection of even the great quantity of food that passes through this port. During the year 89 tons of meat, 161 tons of canned goods, 1217 tons of fruit (partly due to a dock strike), and 3537 tons of cereals were found unfit for human consumption. As much as possible is released to be made up into poultry food, dog biscuit, and the like. In all, 5017 tons of food were condemned, but apparently all this material was utilised in one way or another, though not for food.

Dr. A. B. McMaster, medical officer of health for *Dover*, in his annual report for 1924, states that 3138 brown rats were caught in the town on bird-lime or in traps, 409 in the port, and 32 on board ships. During the year half a million passengers arrived from abroad, of whom 136,607 were aliens. Only two are mentioned as suffering from infectious diseases, one with measles and the other with enteric fever. The import trade of the port is chiefly concerned with fruit and yeast from France, and rabbits, yeast, and poultry from Belgium. Of 35,000 tons of foodstuffs landed 15 tons were condemned. With regard to the health of the town itself, Dr. McMaster reports that the number of families occupying only one or two rooms is increasing, owing to lack of housing. There was in his area in 1924 a milk-borne epidemic of enteric fever, due to the *Bacillus paratyphosus* B;

50 cases were notified, with one death. The source was with difficulty discovered, but the following story was finally elicited. Four retailers got milk from farm B; the report on this milk proved unsatisfactory. At this point Farmer B admitted that the milk came from his brother's farm, C. So now, late, the staff of farm C had to be examined. Farmer C and one of the milkers were found to be carriers, and would take no measure of security till forced, which meant further delay. The epidemic would have been much less extensive had there been water carriage of sewage at the farm, or if the milk had been properly cooled, or if there had been facilities for the washing of hands before milking—in other words, greater cleanliness. Dr. McMaster insists that clean milk can be produced on farms even if the buildings are old, provided that methods of thorough cleanliness are rigidly followed, and that if milk were sent clean from the farms pasteurisation would be unnecessary. The Necessitous Milk Scheme supplied 201 persons in 148 families, 15 taking dried milk.

Dr. A. N. Stevens, medical officer of health for *Great Yarmouth*, states the death-rate in 1924 as 10·8, infantile mortality-rate 63, birth-rate 18. Most deaths (48 per cent.) occurred after the age of 65. Malignant disease and heart disease each caused 77 deaths, and tuberculosis 62. Infectious disease did not call for any school closure in this year. The chief imports are timber and salt from abroad, stone and grain coastwise; the export is fish. Amongst other foodstuffs, 33 tons of fish were condemned and destroyed. 2403 rats were killed, apparently none in ships or in the port. A rat-catcher has been set to work under the rat officer. Sixty-two vessels were disinfected, and, apart from foul pickle, uncleanliness was the chief cause of complaint against ships inspected. The canal boats were all found clean and well kept.

MENTAL HOSPITAL REPORTS.

THE eleventh annual report of the *General Board of Control for Scotland* includes notes of each of the Royal, district, and private institutions in that country, most of which have already been reviewed in these columns. The general survey remarks on the increase in the number of voluntary boarders, and the gratifying fact that parish councils are showing an increasing tendency to pay the cost of voluntary boarders in district asylums, believing that early treatment on this basis may prevent patients from becoming permanent burdens on the rates. Edinburgh Parish Council has arranged for the Royal Edinburgh Asylum to supply 20 beds for voluntary inmates. The undesirable custom of confining adult mental defectives in asylums still continues, but there is evidence of change. The care of the mentally defective is essentially an educational, rather than a clinical or curative, matter, and the two types of mental care do not conveniently go together. It is hoped that the contemplated scheme for the establishment of colonies for adult defective patients will reduce the practice to a minimum. The report suggests the addition of a children's ward attached to the observation wards of infirmaries, for the reception of cases such as encephalitis lethargica. The aim of the Board is to bring their institutions up to the level of general hospitals, and they are able to record that practically every institution in Scotland has a thoroughly equipped dental room and the services of a visiting dentist, while the appointment of specialists in varying branches of medicine is proceeding. Bangour Asylum, which had the advantage of inheriting the most modern treatment apparatus installed when the building was used as a war hospital, has submitted plans for a pavilion where all varieties of hydrotherapy and light treatment will be provided. The problem of typhoid fever in asylums[1] is referred to in the report. The number of carriers in Scottish asylums is now 16, and elaborate precautions have been taken in disinfection and distribution of under-clothing and bed-linen. The institution where the majority of the carriers are resident is considering the erection of a separate villa for these cases. The statistical tables deal with 18,398 insane patients and 2452 mental defectives.

The *Down District Lunatic Asylum* at Downpatrick publishes an illustrated report. The average number resident during the year was 712; there was a slight decrease in the number of admissions on last year's figure. The majority admitted were melancholic, maniacal and delusional cases being next in number. The recovery-rate was 52·4 per cent. and the death-rate 5·9 per cent., a record figure for this institution. The dentist appointed last year has already treated 261 patients, including 1111 extractions. Two sets of wireless have been installed, and are much appreciated. Nine nurses obtained the M.P.A. certificate during the year, and the new regulations insist on attendants and nurses preparing for these examinations.

Hereford County and City Hospital at Burghill has 470 patients in residence, and, unlike most county hospitals, has a certain amount of vacant accommodation. The death-rate for the year has been 7·5 per cent. and the recovery-rate 20·0 per cent., with a further 10·9 per cent. discharged relieved. The arrears of dental work have been overtaken, and the dentist now finds one visit a month sufficient. A cinema apparatus is to be installed in the near future.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 5TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 32; scarlet fever, 1363; diphtheria, 738; enteric fever, 85; pneumonia, 116; puerperal fever, 44; cerebro-spinal fever, 8; acute poliomyelitis, 12; acute polio-encephalitis, 3; encephalitis lethargica, 43; continued fever, 14; dysentery, 6; ophthalmia neonatorum, 98. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 6 deaths from enteric fever, 22 from measles, 5 from scarlet fever, 28 from whooping-cough, 11 from influenza, and 10 from diphtheria. There were 290 deaths of children under 2 years from diarrhœa and enteritis, as compared with 218, 177, 136, and 108 in the preceding weeks. In London itself the deaths from diarrhœa and enteritis in children under 2 years numbered 88, as compared with 40, 28, 20, and 19 in the preceding weeks; there were 10 deaths from diphtheria, 5 from whooping-cough, and 1 from influenza.

DONATIONS AND BEQUESTS.—Mrs. Mary Ogden, who left £12,480, besides other bequests, gave £100 each to the Cottage Hospital, Colwyn; the Manchester Institution for the Blind; Manchester Institution for the Deaf and Dumb; the Cancer Hospital, Manchester; Manchester Ear Hospital; and the Oldham Institution for the Blind. The residue of her property she left to Oldham Infirmary and the Manchester Royal Infirmary.—Mr. William Wright Warde-Adam, of Frickley Hall, Doncaster, left £2000 to the Royal Infirmary and Dispensary, Doncaster; £1000 to the General Infirmary, Leeds; £500 to the Yorkshire Institution for the Deaf and Dumb, Doncaster.—Mr. James Sutcliffe, of Rochdale, left £1000 to the endowment fund of the Rochdale Infirmary and Dispensary, to be known as the "James Sutcliffe Bequest," and £1000 to the endowment fund of the Manchester Royal Infirmary, to be known as the "James Sutcliffe Bequest."—Mr. Sydney Mason, of Anglesey and Ashton-under-Lyne, left as a contingent reversion £15,000 to St. Dunstan's Hostel for Blinded Sailors and Soldiers.—An anonymous gift of £1500 has been made to the Sheffield hospitals.—Alderman Walter Henry Barrett, of Pendleton, left £1500 to the Royal Hospital, Salford, for the endowment of a bed.—Mr. Frank Atkin, of Sheffield, left £500 to the Sheffield Royal Infirmary, and £250 each to the Sheffield Royal Hospital, the Jessop Hospital for Women, the Sheffield Institution for the Blind, the Sheffield University, and the Sheffield Society for the Prevention of Cruelty to Animals.—Miss Lilian Suzette Gibbs, F.L.S., of Santa Cruz, Teneriffe, has, among other bequests, left to the University of London a sum to produce a net annual income of £150 for a studentship in cancer research, either on the physiological or the chemical side, to be called "The Laura de Saliceto Studentship" in memory of her mother.

RHEUMATIC INFECTION IN CHILDREN.

To the Editor of THE LANCET.

SIR,—As in part responsible for the emphasis which has been recently laid on the association between the rheumatic infection in children and poverty, may I say that I used the term "poverty" only as denoting the class of children from which hospital patients are drawn as opposed to that dealt with in private practice. That acute rheumatism in its major forms is overwhelmingly a disease of the former group no one could possibly deny. At the B.M.A. meeting at Bath some criticised the use of the word "poverty" on the grounds that the infection is not so particularly common in the children of destitute and out-of-work families as in those of the working artisan class. With the truth of this I altogether agree, though I do not yet understand the reason of it. But it seems a pity to me to obscure the main issue by quibbling over the term "poverty"; surely this is broad enough to carry the sense of the contrast we desire to stress.

For the point is a very important one. Of all the outstanding rheumatic problems there is none of greater importance than that of the environmental influences which predispose to the infection in children, and here we have one great fact to go on—namely, the predilection of the disease for the poorer classes. Let us, therefore, do nothing to obscure this fact. In opening the debate on rheumatism at the Medical Section of the Portsmouth B.M.A. meeting two years ago I particularly emphasised the significance of this association and appealed to workers in public health to find out and tell us the reason of it. At the Bath meeting this year the Public Health Section met the Children's Section in a discussion on the rheumatic problem, and told us of their investigations. It was their presence which made the meeting so different from any previous ones, so significant and encouraging.

I am, Sir, yours faithfully,
REGINALD MILLER.

Harley-street, W., Sept. 12th, 1925.

QUININE IN PNEUMONIA.

To the Editor of THE LANCET.

SIR,—A record of over 200 cases of lobar pneumonia in the Wano Agency, North-West Frontier Province, India, treated with intravenous injections of quinine bihydrochloride, may be of more than local interest. In 1923–24 the death-rate of pneumonia in this agency was very high. It was noticed that there was a high incidence of malaria in the summer, followed by a high death-rate of pneumonia in the winter. As no other form of treatment seemed to lower the death-rate, I resolved to try intravenous injections of quinine. It was found that they had a very beneficial effect. The temperature came down, the restlessness subsided, and the pulse got better and stronger.

As soon as a case was diagnosed as pneumonia a blood film was taken (which by the way in every case was negative for malaria parasites) and intravenous quinine gr. 7 in 10 c.cm. distilled water given. Another injection was given on the third day, and another on the fifth day, after which no more were given. No injection was given during the crisis. Quinine did not shorten the course of the disease or expedite the crisis. In about 50 per cent. of cases the crisis did not take place till the seventh or eighth day. If the pulse was weak quinine was given with 5 minims of adrenalin.

The following points were noticed:—

(1) That patients with enlarged spleens, due to malaria, did not stand a good chance with the quinine treatment.

(2) That when *too much* quinine was given it had a tendency to make the sputum very viscid, and there was difficulty in expectoration. This was counteracted by tr. jaborand., ♏x, added to mist. stim. expect., ℥i.

(3) That quinine given when the crisis was expected had an unfavourable effect on the heart. The pulse was weak and thready, and the patient showed a tendency to collapse.

(4) That quinine injections given judiciously and in moderate doses definitely had a good pneumococcicidal effect on the disease even in very severe cases of double pneumonia.

(5) The mortality of chronic malaria cases was more than that of non-malarial cases, who had been free from fever during the summer.

The result of the injections was as follows: In Sarwakai, out of 40 cases of lobar pneumonia, there were three deaths only. In Sararogha (civil), out of 22 cases, there were three deaths. In Jandola there were no deaths amongst the first 30 cases treated, while the average of deaths amongst the remainder was 15 per cent. Those were very bad cases of pneumonia. On the other hand, in the brigade at Sararogha, where the cases of pneumonia were not treated by quinine, the case mortality averaged 25 per cent.

I am, Sir, yours faithfully,
R. KHAREGAT, M.B.,
Captain, I.M.S.; Agency Surgeon, Wano.

THE "COMMON COLD."

To the Editor of THE LANCET.

SIR,—The season of "colds" is at hand; indeed, an epidemic has been already reported. It is a curious fact that the general public has not realised that the common application of the word "cold" is a complete misnomer and, moreover, actually misleading. There is a disarming simplicity about the word, and in the public mind it is associated with "draughts," "cold winds," and so forth, and the idea is inherent that prevention and even cure lie in the piling on of additional clothing.

No doubt there is some connexion with atmospheric conditions, but the public mind has entirely failed to grasp that the symptoms which are grouped together under the name of a "cold" are due to invasion of the system with micro-organisms of varying virulence, and that the results of such invasion are often disastrous. The lengths of the obituary columns in the daily papers during the winter are due mainly to deaths from respiratory complaints, many of which owe their origin to the common cold, and, in addition, it is well known to the medical profession that numerous chronic and disabling diseases can be traced to the same source.

In consequence of this want of knowledge among the community few or no precautions are taken against spreading infection. Sufferers from "only a cold" fulfil their social functions as usual, and attend places of worship and of entertainment, quite regardless of the dangers to which they are subjecting their neighbours. The circumstances of many people suffering from colds are such that it is quite possible for them to remain in bed for the first few days, and if only they would do so, not only would their own disability be shortened, but many susceptible persons would be spared a similar infection. Moreover, it is certain that if such a course could be *generally* followed, the *total* number of "lost working days" would be diminished very appreciably.

The time is ripe for a campaign by the health authorities against a complaint whose effects are so far reaching, but the first stage in such a campaign against the "common cold" and its unrealised dangers must be the discarding of its present name and the substitution of another more expressive of its actual nature.

I am, Sir, yours faithfully,
JOHN ALEXANDER DRAKE, M.D. Lond.,
D.P.H.

Harley-street, W., Sept. 12th, 1925.

Obituary.

WILLIAM ODELL, M.D. DURH., F.R.C.S. ENG.

BY the recent death of Dr. William Odell, of Torquay, in his seventy-fifth year, the medical profession has lost a fine example of all that was best in the "old school" of family practitioners. William Odell was educated at St. Paul's School, Stony Stratford, and at Hertford Grammar School. He received his medical education at St. Bartholomew's Hospital, qualifying as licentiate of the Society of Apothecaries in 1872. He gained the M.R.C.S. Eng. in the same year and the Fellowship four years later, when resident surgical officer at Hertford County Hospital. In 1901 he became M.D. Durh. After holding hospital appointments for five years, he took up private practice in Hertford in 1878 and later in Toronto, until in 1880 he settled in Torquay. Dr. Odell held the appointments of honorary consulting physician to the Western Hospital for Consumption, honorary consulting surgeon to the Erith House Institute, and honorary physician to the Temple Lodge Home. He was an honorary life member of the St. John Ambulance Association, and did much work in connexion with the Epsom College Foundation, of which he was local secretary. During the war he was physician to the Western Auxiliary Military Hospital in Torquay. Throughout his professional career he took an active interest in medical education and politics, and was at one time president of the Torquay Medical Society. Dr. Odell made several contributions to medical literature, particularly with regard to the treatment of tuberculosis.

THE LATE DR. R. B. ESKRIGGE.—Richard Bertram Eskrigge, L.R.C.P. Edin., M.R.C.S. Eng., of Royston, Barnsley, Yorks, died on August 31st in his sixty-third year. He received his medical education at the Manchester School of Medicine, qualifying as L.R.C.P. Edin. in 1883, and obtaining the membership of the Royal College of Surgeons of England in the same year. For 37 years he practised in Royston, where he was held in the highest esteem.

THE LATE DR. G. LOVE.—Gilbert Love, senior, M.D. Belf., of Great Budworth, Cheshire, died at the age of 60 on Sept. 6th, as the result of a distressing accident when on holiday at Downpatrick in the north of Ireland. While out shooting, he passed through a hedge and a twig released the trigger of his gun, with the result that the charge shattered his leg. He lay bleeding for some time before he was removed to the local infirmary, where the limb was amputated. Dr. Love, who was one of the best-known practitioners in Cheshire, studied at Queen's College, Belfast, where he gained the medal in midwifery and diseases of women. He graduated M.D., Ch.B., B.A.O. in the Royal University of Ireland in 1888, and after serving as medical and surgical assistant in the Royal Hospital, Belfast, settled in Northwich, where he had an extensive practice, and was honorary surgeon to the Victoria Infirmary of that town. Dr. Love was a prominent Freemason, being Provincial Officer and Past Master of the Sincerity Lodge, Northwich. He was chairman of the Conservative Association, the Budworth Fête Committee, and the Northwich Infirmary Medical Board.

THE LATE DR. W. J. LEIGHTON.—William James Leighton, M.D. Belf., of Chorley, Lancs, was found dead beneath his two-seater car on the night of Sept. 8th in Lucas-lane, close to Chorley. The car was overturned broadside across the lane, with lights burning. How Dr. Leighton lost his life is entirely unexplained. Dr. Leighton was 42 years of age and had practised in Chorley for nearly 15 years. He had consulting-rooms in St. Ann-street, Manchester, where he was hon. assistant surgeon in the out-patient department of St. John's Hospital for the Ear and Nose. At Chorley he was hon. medical officer of the Rawcliffe Hospital and hon. secretary of the Chorley Medical Society. He received his medical education at Belfast and Dublin, and in 1906 graduated M.B., B.Ch., and in 1909 obtained the degree of M.D. at Belfast. Before going to Chorley he was house surgeon to Bedford County Hospital and resident medical officer of the Belfast Corporation Fever Hospital, and resident clinical assistant at the Richmond Hospital, Dublin.

Medical News.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A two weeks' intensive course in medicine, surgery, and the special departments begins on Monday, Sept. 21st, at the Westminster Hospital. On the same day the Brompton Hospital starts a special two weeks' course in diseases of the chest. Beginning in October the Fellowship of Medicine will hold a series of lectures on tuberculosis in the lecture room of the Medical Society, 11, Chandos-street. The first lecture will be given on Oct. 12th, at 5.30 P.M., by Dr. L. S. Burrell, on Tuberculosis from the Physician's Viewpoint. All members of the medical profession will be welcomed. Also during October will be held a special course in diseases of the throat, nose and ear at the Central London Throat, Nose and Ear Hospital (an operative surgery class will be held in addition); a course in tropical medicine consisting of eight clinical demonstrations on Tuesdays and Thursdays; a combined course in diseases of children; a course in urology at St. Peter's Hospital; and a course in dermatology at St. John's Hospital. Copies of any syllabus, together with the Fellowship programme, may be obtained from the Secretary, 1, Wimpole-street, London, W.1.

OPENING OF THE MEDICAL SCHOOLS.—The following functions will be held in connexion with the opening of the undermentioned London medical schools:—

St. Bartholomew's Hospital.—Old students' annual dinner, Thursday, Oct. 1st, in the Great Hall of the hospital. Chairman: Mr. J. Adams.

St. George's Hospital.—The school dinner, Thursday, Oct. 1st, at 7.15 for 7.45 P.M. at the Hyde Park Hotel. Chairman: Dr. Ashton Warner. The Rt. Hon. W. H. Bridgeman will propose the toast of the Medical School.

Guy's Hospital.—Address to the students, Tuesday, Sept. 20th, by Major J. H. Beith ("Ian Hay").

King's College Hospital.—The introductory address, Thursday, Oct. 1st, at 2.30 P.M., by Sir Arthur Keith, at the Medical School, Denmark Hill, S.E. 5. The annual dinner of past and present students will be held at 7 for 7.30 P.M. on the same day at the Connaught Rooms, Great Queen-street, W.C. 2. Chairman: Sir Lenthal Cheatle.

London Hospital Medical College.—Annual old students' dinner, Thursday, Oct. 1st, at 7.30 for 8 P.M., at the Trocadero Restaurant, Piccadilly Circus.

St. Mary's Hospital.—Past and present students' annual dinner, Monday, Oct. 5th, at the Connaught Rooms, Great Queen-street. Chairman: Mr. Leslie Paton.

Middlesex Hospital.—In the Queen's Hall, Thursday, Oct. 1st, at 3 P.M., prize distribution by the Hon. Sir Arthur Lawley; inaugural address by Dr. C. E. Lakin on Tradition in Medicine. Annual dinner, Thursday, Oct. 1st, at the New Criterion Restaurant, Regent-street. Chairman: Sir Arnold Lawson.

St. Thomas's Hospital.—Annual old students' dinner, Friday, Oct. 30th, at the Hotel Victoria, Northumberland-avenue. Chairman: Mr. Samuel Osborn.

University College Hospital.—Annual dinner of past and present students, Oct. 10th, at Hotel Cecil, at 7.30 P.M. Chairman: Dr. Herbert Spencer.

Westminster Hospital.—Inaugural address by Prof. A. B. Gardner, Thursday, Oct. 1st, at 3 P.M., in the board room of the hospital.

CENTRAL LONDON, THROAT, NOSE, AND EAR HOSPITAL.—The opening lecture of the winter session will be given at the hospital, Gray's Inn-road, W.C. 1, on Tuesday, Oct. 6th, at 4 P.M., by Dr. William Hill, who will take as his subject The Practice at "The Central" in the Late 'Eighties; a Period of Marked Advance and Foreshadowing Many Modern Improvements in Technique.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The opening meeting of the next session of this society will be held in the society's rooms at the West London Hospital, Hammersmith, on Friday, Oct. 2nd. The chair will be taken at 8.30 P.M., when Dr. H. W. Armstead will read his presidential address entitled Thirty Years of General Practice.

UNIVERSITY OF DURHAM.—In connexion with the opening of the winter session of the University of Durham College of Medicine, Newcastle-upon-Tyne, an introductory address will be given in the Examination Hall of the College on Tuesday, Oct. 6th, at 4.30 P.M., by Sir Humphry D. Rolleston on Physic and Poetry.

Society of Medical Officers of Health.—The annual dinner of this society will be held at the Piccadilly Hotel on Friday, Oct. 16th, at 7 for 7.30 P.M. Dr. G. F. Buchan, the new President, will be in the chair, and the council hope that members will be present in large numbers. Ladies are invited, and members are asked to give early notice to the executive secretary, 1, Upper Montague-street, Russell-square, W.C. 1, of their intention to be present, with the names of their guests. A payment of 12*s.* 6*d.* for each ticket should be made with applications sent before Oct. 10th; after that date the cost of tickets will be 15*s.* each.

Society for the Study of Inebriety. — The eleventh Norman Kerr memorial lecture will be delivered by Dr. R. Hercod, director of the International Bureau against Alcoholism, Lausanne, Switzerland, on Tuesday, Oct. 13th, at 4 P.M., in the hall of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W. 1, when the subject will be Alcoholism as an International Problem. There will be a luncheon at 1.30 P.M. at the Welbeck Palace Hotel, Welbeck-street, Cavendish-square, W. 1, when Sir William Willcox, President of the Society, will preside, and Dr. Hercod will be present. Tickets 4*s.* each (exclusive of beverages). Members and associates desiring to be present are asked to send intimation to the hon. secretary, Dr. T. N. Kelynack, 19, Park-crescent, Portland-place, W. 1, with remittance before Oct. 7th.

People's League of Health.—The League, by kind permission of the London County Council, will give the Sims Woodhead series of constructive educational health lectures at the Regent-street Polytechnic. The series will commence on Friday, Oct. 9th, at 6 P.M., and be continued on the following five Fridays at the same hour. Among those who have promised to lecture are: Sir Harry Baldwin, Prof. Leonard Hill, F.R.S., Prof. H. R. Kenwood, Mr. E. B. Turner, Prof. M. S. Pembrey, F.R.S., and Prof. B. J. Collingwood. At the conclusion of the series there will be an optional examination for those who have attended the lectures, and certificates will be issued by the Medical Council of the People's League of Health (with a travelling scholarship prize award, consisting of a week's visit to a foreign country, with facilities for visiting its health centres). Tickets and further information regarding the lectures held may be obtained from 12, Stratford-place, W. 1.

Puerperal Fever and the M.A.B.—Arrangements have been made by the Metropolitan Asylums Board whereby in future the cases of puerperal fever referred to the Board will be concentrated as far as practicable in three of their institutions—namely, the Eastern Hospital, Homerton; the North-Western Hospital, Hampstead; and the South-Western Hospital, Stockwell—where special wards will be set aside for these cases and special medical and nursing staffs provided. The Board have also, with the approval of the Minister of Health, appointed an obstetric consultant at these three institutions. A circular (No. 622) has been issued by the Ministry to metropolitan borough councils in which it is recognised that suitable accommodation for cases of puerperal fever is available at other institutions, but expressing the hope that borough councils will take steps to secure, as far as practicable, that full use is made of the accommodation provided by the Metropolitan Asylums Board. The medical officer of health is requested to bring this point to the notice of general practitioners.

Death Certification and Coroners' Law.—In the course of his fourth presidential address to the Sanitary Inspectors Association, which recently held its thirty-eighth annual conference, Sir William Collins referred to the necessity of further reform in death certification and coroners' law. He recalled the disgraceful conditions which obtained during the last century, and speaking of untrustworthy verdicts, referred to the two classical examples: "Death from stone in the kidney which stone he swallowed when lying on a gravel path in a state of drunkenness," and "Child, three months old, found dead, but no evidence whether born alive." Though administration had effected much, legislation still lagged behind. "I remember," continued Sir William Collins, "in 1895, 1896, and again in 1907, voicing deputations to three successive Lord Chancellors, Lords Herschell, Halsbury, and Loreburn, urging reforms in death certification and coroners' law. From all we received promises of sympathetic and serious consideration, but practically nothing has been done. A Bill has, I understand, been introduced this session by a private medical Member dealing with certain reforms in the matter of death certification and disposal of the dead; but in view of a promise made by the Home Secretary of a Government Bill on the whole subject the prospects of the private Member's venture are not roseate. It is to be hoped," he added, "that the Home Secretary's assurances may prove more fruitful than those of the three Lord Chancellors."

Vienna Medical Faculty.—A comprehensive series of post-graduate courses has been arranged by the Faculty for the academic year 1925–26. A full syllabus and information regarding lodging, &c., in Vienna may be obtained from the offices of the Vienna Medical Faculty, Schlösselgasse 22, Vienna VIII. It is requested that the cost of return postage be enclosed with inquiries.

Patients' Payments to Hospitals.—A return issued by the London Hospital Sunday Fund states that last year the payments made by patients amounted to £860,000—almost exactly one-third of the total income (£2,590,000) of the metropolitan hospitals. The expenditure was £2,887,000. Just under half a million was received in legacies, and of the total of 13,625 beds, 11,234 were constantly occupied.

Casualties at the Royal Free Hospital.—Last year 1751 casualties were received, a number exceeded only by one other hospital. The completion of the first portion of the new home for nurses since the report was prepared will make it possible to open shortly single rooms for private patients of limited means.

Leicester Pensions Hospital.—This hospital, which during the war served as the Fifth Northern General Hospital, is to be closed in November. There are rather more than 100 men still there, and it is expected that they will be removed to Birmingham.

Cost of Tuberculous Patients.—The annual report of the Hospital for Consumption at Brompton shows that the average stay of its 2389 in-patients was 49 days, and that the cost per head was £24 7*s.* 10*d.* The 459 in-patients of the sanatorium at Frimley cost £58 12*s.* 4*d.* each. Of the 326 beds at Brompton 280 were constantly occupied.

"A. J. S. Radio" Luncheon.—The initials "A. J. S." are familiar to users of motor-bicycles, and it will not be long before they are equally familiar to users of wireless apparatus. On Sept. 10th "A. J. S. Radio (1914), Ltd." opened their London offices, showrooms, and demonstration rooms, and celebrated the occasion by a lunch. Mr. Edgar E. Lamb presided, and proposed the toast of "Our Guests," which was replied to by Mr. Otto Thomas and Prof. A. M. Low. Whilst manufacturing all sorts of wireless apparatus, including a fine-looking plant stand which is really a loud-speaker set, this company will specialise in compact sets for ordinary listeners-in.

Manchester's Street Accidents: A Poster Campaign.—Statistics for the year ending June 30th show that the number of persons killed in this period in Manchester was 59, 6 of these being at cross-roads, 11 at the approach to cross-roads, and 11 at the junction of side streets and main streets. The number of fatal accidents caused by stepping off the pavement in front of approaching vehicles was 21, involving 24 private motor-cars, 24 other mechanically-propelled vehicles, 7 tramcars, 4 taxi-cabs, and a number of other vehicles. In the non-fatal accidents 1855 persons were injured. Of these accidents 376 occurred at cross-roads, 493 at the junction of side streets and main roads, and 524 at other points. 427 of the accidents occurred through persons stepping off the footpath in front of approaching vehicles. In the non-fatal accidents were involved, among other vehicles, 588 private motor-cars, 380 other mechanically-propelled vehicles, 303 tramcars, and 70 taxi-cabs. Eighteen persons were hurt in pillion-riding accidents. On the suggestion of the chief constable it has been decided that the city shall be placarded with large posters warning against the dangers of street traffic, and also that posters warning children shall be placed on public buildings and on all schools in the city. Small forms containing warnings will be distributed to applicants for motor drivers' licences and to motorists' organisations. Similar forms will be supplied to the Director of Education for distribution to all the schools in the city, for the use of teachers so that they may consistently bring these safety rules to the notice of their scholars. There are injunctions to be observed by motorists—what they should do and not do, and a code for pedestrians. From the pedestrian's point of view perhaps the best thing in this poster is this: "Stand, look, and listen before crossing the road." The slogan "stand, look, and listen" ought to be memorised and practised by every pedestrian.

CONVALESCENT HOME FOR MERCHANT SEAMEN.—The Seamen's Hospital Society has for seven years maintained a convalescent establishment, the "Angas Home" at Cudham, near Orpington, Kent, for recovered patients discharged from the society's hospitals in London, but it has recently been found necessary to extend the accommodation. Such extension was made possible by the continued interest of Mrs. L. G. Angas, who gave the original house to the society in 1918, and on Sept. 11th a number of friends of the society gathered at Cudham, when Sir Arthur Clarke, chairman of the committee of management, asked Mrs. Angas to open the new buildings with a presentation gold key. In replying to a vote of thanks proposed by Admirals Sir Henry Jackson and G. R. Mansell, Mrs. Angas said she was glad to provide an extension to the buildings in memory of Captain the Rev. H. W. Angas, who devoted himself to relieving the hardships of seamen. Sir A. Clarke mentioned that, like the other establishments of the society, this building was now opened free of debt, but that £80,000 was wanted annually to keep the work going, and that subscriptions were welcomed. The home is a remodelled and extended country house, now able to take 40 patients, none of whom is chronic, in large grounds with lawns, trees, and gardens, 600 feet above the sea. Of the 40 beds, two, in separate rooms, are for officers; the others are in wards of various sizes. There are smoking rooms and a large billiard room with a piano and stage.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 21st, to SATURDAY, Sept. 26th.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross, W.C. Clinical demonstration every afternoon from 2 o'clock, with special demonstrations three times a week.—WESTMINSTER HOSPITAL, S.W. Special Post-graduate Course in General Medicine and Surgery, and the special departments. 10.30 A.M. to 5.30 P.M. daily. Demonstrations, lectures, &c. (first week).—HOSPITAL FOR CONSUMPTION AND DISEASES OF CHEST, Brompton, S.W. Post-graduate Course in Diseases of the Chest. Operations, lectures, lecture-demonstrations, demonstrations of surgical cases, of cases in wards, and in special departments (first week).—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Lecture-demonstration on Treatment by Electrotherapy on Wednesday, Sept. 23rd, and the three succeeding Wednesdays, at 5.30 P.M., by Dr. C. B. Heald. The Direct Current especially in Relation to Fractures and Injuries.

Appointments.

BINDLOSS, E. F., L.R.C.P. Lond., M.R.C.S., has been appointed Poor-law Medical Officer for Farnborough, Hants.

JONES, H., L.R.C.P. Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for the Maesteg District of the County of Glamorgan.

OGILVIE, W. H., M.D., M.Ch. Oxf., F.R.C.S. Eng., Assistant Surgeon to Guy's Hospital.

SAVORY, MARGARET B., M.B., B.S. Lond., House Surgeon to the New Sussex Hospital for Women and Children, Brighton.

Royal Northern Hospital: HUNTER, J. B., F.R.C.S. Eng., Surgeon, and BUTLER, H. O'NEIL, L.D.S. R.C.S., Assistant Dental Surgeon.

The Royal Alexandra Infirmary, Paisley: CALDWELL, J., M.B., Ch.B. Glasg., Senior Resident House Physician; POLLOCK, A. M., M.B., Ch.B. Glasg., Resident House Physician; MACARTHUR, J. C., M.B., Ch.B. Glasg., and GUNN, D., M.B., Ch.B. Edin., Resident House Surgeons.

Vacancies.

For further information refer to the advertisement columns.

Barnstaple, North Devon Infirmary.—H.S. £150.
Battersea General Hospital, S.W.—Med. Supt. £300.
Birmingham General Hospital.—Asst. S. £50.
Blackburn County Borough.—Asst. M.O.H. £600.
Buxton, Derbyshire, Devonshire Hospital.—Asst. H.P. £150.
Carmarthenshire Education Committee.—Asst. Sch. M.O. £600.
Chelsea Hospital for Women, Arthur-street, Chelsea, S.W.—S.
Colchester, Essex County Hospital.—H.P. £200.
Denbigh County Council.—Asst. M.O. £600.
Durham County Council.—Asst. Sch. M.O. £600.
East Ham County Borough Education Committee.—Temp. Asst. Sch. M.O. At rate of £600.
Edinburgh, Scottish Board of Health.—Dist. M.O. £1000.
Evelina Hospital for Children, Southwark, S.E.—H.P. At rate of £120.
Glasgow Royal Infirmary.—Supt. £800.
Hôpital Français, 172, Shaftesbury-avenue, W.C.—Sen. and Jun. Res. M.O.'s. £120 and £100 respectively.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Res. M.O. and H.P. At rate of £150 and £100 respectively.
Leeds Public Dispensary.—Jun. Res. M.O. £150.
Liverpool, David Lewis Northern Hospital.—Med. and Surg. Tutors and Registrars.
Macclesfield, Cheshire County Mental Hospital, Parkside.—Asst. M.O. £350.
Manchester, Ancoats Hospital.—Asst. Surg. Reg. £40.
Manchester and District Radium Institution.—Asst. Radiologist. £500.
Mental Hospitals Service under the L.C.C.—Eighth Asst. M.O. £432.
Miller General Hospital for South-East London, Greenwich, S.E.—H.P. £125.
Norfolk County Council.—Asst. Tub. O. £600.
Radium Institute, 16, Riding House-street.—Cancer Research Worker. £500.
Royal London Ophthalmic Hospital, City-road, E.C.—Refraction Asst. £100.
St. Bartholomew's Hospital and College.—Res. Asst. Phys.-Accoucheur and Demonstrator of Pract. Midwifery.
St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.—Clin. Assts.
South London Hospital for Women, South Side, Clapham Common, S.W.—H.P., three H.S.'s. Each at rate of £50. Clin. Asst. £1 1s. per attendance. S. to Ear, Nose, and Throat Department.
South Shields County Borough.—Ven. Diseases M.O. £750.
South Shields, Ingham Infirmary.—Jun. H.S. £150.
Throat Hospital, Golden Square, W.—Two H.S.'s at rate of £100. Also Hon. Surg. Reg.
Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £100.
Whalley, near Blackburn, Calderstones Certified Institution for Mental Defectives.—Asst. M.O. £300.
Whipps Cross Hospital, Leytonstone.—Specialist Consultant in Light Treatment. £300.
Willesden General Hospital, N.W.—H.S. At rate of £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments for Certifying Factory Surgeons at Nairn, Nairnshire, and Guildford, Surrey.

Births, Marriages, and Deaths.

BIRTHS.

HALES.—On Sept. 12th, at Lees Lodge, Sheringham, Norfolk, the wife of Henry Ward Hales, M.D., of a daughter.

HART.—On Sept. 8th, at Platt's-lane, Hampstead, the wife of S. L. Hart, L.D.S., of a daughter.

HASLETT.—On Sept. 6th, at Holmbank, Upper Halliford, Shepperton, the wife of Dr. W. Handfield Haslett, of a son.

HAWLEY.—On Sept. 11th, at Hazelbeech, Coventry, the wife of Thomas Hawley, F.R.C.S., of a son.

MOLLISON.—On Sept. 12th, at Devonshire-place, London, the wife of W. M. Mollison, M.Ch., of a son.

MARRIAGES.

ALLISON—STEEN.—On Sept. 9th, at Fitzroy-avenue Church, Belfast, Richard Sydney Allison, M.D., M.R.C.P., to Elizabeth Nowell Barnett (Betty), younger daughter of Mr. and Mrs. J. Barnett Steen, Eglantine-avenue, Belfast.

HOSFORD—RANDALL.—On Sept. 8th, at All Saints Church, Ryde, Reginald Walter Patrick Hosford, M.B., F.R.C.S., to Nora Kathleen, daughter of Mr. and Mrs. F. W. Randall, of Mayfield, Ryde.

MICHELMORE—CHILTON.—On Sept. 7th, at Salcombe Regis, Ralph Godfrey Michelmore, M.B., B.S., of Sidmouth, to Charlotte Macintyre Chilton, youngest daughter of Mr. and Mrs. Charles Chilton.

MORGAN—MITCHELL.—On Sept. 11th, at University Chapel, King's College, Old Aberdeen, George Roderick Morgan, M.C., M.B., Ch.B., second son of George Blacker Morgan, M.D., Sunderland, to Betty Mitchell, M.B., Ch.B., youngest daughter of Peter Mitchell, M.D., Old Aberdeen.

SHORE—HOARE.—On Sept. 12th, at St. Bartholomew the Great, Smithfield, Thomas Henry Gostwyck Shore, M.D., M.R.C.P., to Viola Edith, second daughter of the late Mr. Frederick Hoare, of Craiglands, Crouch End Hill, and Mrs. Hoare, of Stanhope-gardens, Highgate, N.

THOMPSON—WILKIE.—On Sept. 8th, at the Parish Church, Falmouth, Brian G. Thompson, M.D., to Elsie Katharine, daughter of Colonel D. Wilkie, Indian Medical Service (retd.), and Mrs. Wilkie, of Coolmore, Falmouth.

YOUNIE—MITCHELL.—On Sept. 11th, at University Chapel, King's College, Old Aberdeen, John Younie, Indian Civil Service, son of Mr. George Younie, Rothes, to Dorothy Mitchell, M.B., Ch.B., D.T.M., eldest daughter of Peter Mitchell, M.D., Old Aberdeen.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

SOME ACHIEVEMENTS OF INDUSTRIAL LEGISLATION AND HYGIENE.

Being an Address delivered to the Congress of Industrial Hygiene, Amsterdam, Sept. 12th, 1925,

BY SIR THOMAS OLIVER, M.D. GLASG.,
PRESIDENT OF THE BRITISH SECTION.

INDUSTRIAL hygiene is a comparatively recent branch of medicine. Although Ramazzini published his treatise on "Occupation Diseases" in 1700, it was the utilisation of steam as a motive power which stimulated the growth of modern industry. The manufacture of pottery, also of bricks for building purposes, is one of the oldest trades. Coal-mining, on the other hand, is one of the most important industries as it is one of the most dangerous. The Romans during their occupation of Great Britain made use of the coal obtained from "drifts" in the city and neighbourhood of Newcastle-upon-Tyne. There was no deep mining for coal in those days. It was in the early part of the thirteenth century that permission was granted by Henry II. to dig for coal in the North of England. During the early part of last century coal-mining in Great Britain was a procedure attended by great hardships, physical and social, upon those who followed the vocation. A hundred years ago the hours of work were long, 12 to 13 per day, boy labour was exploited, and female labour underground was utilised; there was only one shaft leading into the mine, which served both for men and material, and, as a consequence, not only was there no "through ventilation" of coal-mines, but in the event of the single shaft becoming blocked there were no means of escape for the men underground or their comrades above ground reaching them. It was the occurrence of such an accident at a pit a few miles from Newcastle, known as the Hartley Colliery Disaster, 60 years ago or thereabouts, which led to the compulsory provision of two shafts into a mine whereby there is the "through ventilation" which is in use to-day. The winning of coal has always been a hazardous occupation. It was therefore to be expected that the risks and dangers to life in coal-mining through accident and illness, also the long hours of work, would at the earliest opportunity engage the attention of the British Parliament.

Two months ago I was called professionally to see a retired coal-miner, aged 72, who told me that he began work in the mine at the age of 9; that he worked from 4 A.M. till 5 P.M., and for this 13 hours work per day he received 10*d*. He had to be wakened at 3 A.M., left the house at 3.30 A.M., and had to walk more than a mile to the mine where at the pithead he was obliged to be ready to descend at 4 o'clock in the morning. He often slept while he walked to and from his work, and like the boys younger than himself employed in the mine, he frequently fell asleep at his work, and for which he was ill-treated by the foreman. In the winter months collier boys never saw daylight except on Sunday. It is an interesting fact that as recently as the last decade of the eighteenth century, miners and salters—that is, men who obtained salt from sea-brine—were, practically speaking, serfs in Scotland. Those men could be bought and sold along with the purchase and sale of mines. It was not until 1799 that they received their freedom. The circumstance just mentioned may to some extent explain the deplorable conditions which prevailed in coal-mining in the early years of last century in Great Britain, also the unsatisfactory housing of coal-miners and their families.

Fatal Accidents.

It is impossible to say what the number of fatal accidents was three-quarters of a century ago, for statistics at that period were not kept, but the death-roll was heavy. Before 1814 it was not the custom for inquests to be held on colliers who met their death by an accident in the mine. As showing the death-rate from mine accidents during the latter half of 1800, the following data supplied to me by Prof. H. Louis, of the Mining Department, Armstrong College, are of interest. Taking quinquennial periods, the death-rates from mining accidents per 1000 men employed underground in Great Britain were:—

Year.		Year.	
1851–55	5·149	1876–80	2·709
1856–60	4·628	1881–85	2·312
1861–65	3·791	1886–90	2·042
1866–70	3·995	1891–95	1·704
1871–75	2·736	1896–99	1·479

If we take two later decennial periods for comparison, we find that the average annual deaths from accidents in British mines due to all causes were: 1873–82, per 1000 men employed 2·5, and from 1911–20 1·3.

With the exception of the United States of America the statistics of other countries also show a decline in the accident fatality-rates.[1] In Germany the rate, which was 3·18 per 1000 men employed in 1879, had fallen to 2·40 in 1914; in the United States the fatal accident-rate had risen from 3·5 per 1000 in 1890 to 3·62 in 1920, while during 1920 the rate for Belgium was 1·13, France 0·77, Great Britain 0·88, and 2·40 for Germany. Coal-mining in the United States is a comparatively modern industry; the men have not been so long trained as those in the older countries. In addition, many foreigners are employed and, as a consequence of difficulties incidental to language, orders given by officials may not be readily understood. The men, too, in order to make high wages work harder than in most countries. If the accident-rate is measured by the number of men killed for every million tons of coal raised, the figures for the United States compare most favourably with those of other countries.

Coal Mining.

Speaking generally for all countries, but especially for my own, the figures show that improvement has taken place in the reduction of fatal accidents in coal-mining, largely consequent upon freer ventilation, daily inspection of the mine for gas before the men descend, greater use of safety-lamps, substitution of the higher explosives for ordinary black gunpowder, also the employment of skilled men to place in situ the cartridges and fire them.

Although one of the most dangerous of occupations, coal-mining in Great Britain remained free from protective legislation until 1842, when owing to the serious condition of affairs revealed by a Royal Commission, women and girls were excluded from working underground. It was not, however, until 13 years afterwards that measures were introduced to protect the health, life, and limbs of the workers. For the saving of life in coal-mines we are indebted to the attention given to the subject by men engaged in chemical and physical research. The employment of the "safety-lamp" recommended by Sir Humphry Davy has prevented many explosions, just as the daily inspection by trained men of the areas at the working face of the mine before commencing to hew coal has been the means of saving many a miner from getting "gassed." One other important circumstance has added considerably to the safety of the miner's vocation. Three-quarters of a century ago the dangers of explosive gases in coal-mines had been recognised, but it was not until a few more decades had passed that Prof. Galloway and Mr. H. Hall showed that as widespread explosions frequently followed the firing of cartridges in mines, some of these explosions were due to the dry coal-dust which was raised into the atmosphere catching fire and travelling with explosive rapidity through the underground passages. Men were thus killed partly by gas, partly by burns, and in other instances, where death was not immediate, by pneumonia. Coal-mining on a large scale in France, Belgium, and Germany is of recent date compared with that of Great Britain. It was not, for example, until 1766 that coal-mining in Westphalia became a prominent industry. Other coal-producing countries have profited by the experience, the mistakes, and failures of British mining methods. As an illustration of how hygienic measures introduced to protect the workers in one direction may inadvertently lead to disaster in another, I cannot do better than reproduce the experience of the German mining authorities in the Ruhr a few years ago. Before the war several of the coal-mines in Central and Western Europe had become infected by ankylostomiasis. I visited the Belgian, German, and Hungarian coal-fields, and I descended into the Lothringen Mine near Bochum. I was much impressed by the excellent organisation, the sanitary measures which had been carefully prepared by Dr. Tenholt, and the adequate hospital provision made by the mine authorities for combating the disease in Westphalia. Although the parasite had gained entrance into the tin-mines of Cornwall, British coal-mines, fortunately, remained free. Ankylostoma ova and larvæ require heat and a considerable amount of moisture for their development. A few years previously to my visit to Westphalia there had occurred explosions in the German coal-mines for which high temperatures and the dry coal-dust were partly believed to be responsible. With the view of reducing such risks it was decided to introduce water-spraying into the mines. This, however, only caused fresh trouble, for the mines became infected by the ankylostoma parasite, which it was believed had been brought thither by Polish and Italian workmen, also probably by some of their own miners who during the summer months had worked in the brickfields

around Cologne and elsewhere. At any rate, in 1900 water-spraying of mines became general and the result was as follows:—

---

[1] Kober: Industrial Hygiene, p. 145.

Year.	Cases of ankylostomiasis.	Year.	Cases of ankylostomiasis.
1896	107	1899	275
1897	118	1901	1030
1898	99	1903	1355

The rapid and great increase in the number of cases of ankylostomiasis after water-spraying can hardly be regarded as a coincidence.

As a class, coal-miners suffer less from pulmonary tuberculosis than most men employed in dusty occupations, but as Prof. E. L. Collis[2] remarks, "low as their phthisis mortality is, the experience for coal-miners displays certain statistical characteristics which are distinctive of dust phthisis," and these are "(1) an unusually late age of maximum incidence, and (2) an association with high mortalities from other respiratory diseases." Miners who are working at the coal face suffer from phthisis rather more than other miners below ground and workers above ground. Phthisis in coal-miners commences to express itself at and after 35 years of age, as the following figures show:—

Periods.	Age periods—			
	35	45	55	65 and over.
1890–92	1·45	2·07	2·22	2·03
1900–02	1·09	1·52	2·04	1·47
1910–12	1·02	1·31	1·43	1·02

The above data show the improvement which has taken place in the mortality-rate of coal-miners from phthisis.

Manufacture of Lucifer Matches.

There must be many in this audience who like myself, 20 to 30 years ago, were witnesses of the ill-health experienced by men and women who worked in match factories wherein white phosphorus was used. The men who dipped the matches in the phosphorus paste and the women who filled the boxes frequently suffered from necrosis of the jaw-bones or died from septic meningitis or broncho-pneumonia. In other instances where the poisoning was less severe the workers suffered from gastric trouble, anæmia, and albuminuria, or from a tendency of the long bones to become fractured owing to peculiar fragility. So great was the suffering of the persons who became affected that it became imperative that some united action should be taken by various Governments to produce matches which would strike anywhere without the workers incurring risk to their health. As far back as 1879 Switzerland introduced a Bill to prohibit the use of white phosphorus. In 1898 the British Government invited Sir Edward Thorpe, Dr. Cunningham, and myself to visit match works at home and abroad with the view of ascertaining how the workers might be protected against the risks they were exposed to. Like many of our Continental confrères, we were of the opinion that the time had come when a harmless substitute should be found for the dangerous white phosphorus. It was Lorinser, of Vienna, who in 1845 first drew attention to necrosis of the jaw-bones as an occupational disease, but in every country in which lucifer matches had been made from white phosphorus there had occurred cases of "phossy jaw." Chemists vied with each other to find a safe substitute for the dangerous metalloid. To French scientists fell the honour of showing how by employing sesquisulphide of phosphorus lucifer matches could be made without risk to the health of the workers. After a congress of the various Governments held in Berne in 1906, the match-producing countries of Western Europe decided to manufacture lucifers by the safe method, and so successful has been the result that the occupation is now free from the risks of three decades ago. Phosphorus necrosis has disappeared. This is one of the triumphs of industrial hygiene of which chemistry and medicine may well be proud and for which we are indebted to France.

Manufacture of Mirrors.

Chemical research has also proved helpful in other trades. It is not so long ago since quicksilver was used in the manufacture of mirrors. Many of the men then employed suffered from mercurial poisoning. Apart from the unhealthy conditions set up in the mouth through vaporisation of quicksilver, the workers became the victims of muscular tremor and occasionally of paralysis. Since making use of nitrate of silver preparations the men have had good health and the industry is now regarded as a healthy one.

Arsenical Pigments.

Just over 20 years ago I was a member of the Dangerous Trades' Committee of the Home Office to whom was given the task of investigating several trades which were regarded as inimical to health. One of these was the manufacture and use of wall-papers which contained arsenic, also the manufacture, mixing, and use of "emerald green." It had been found that much illness hitherto unrecognised was the result of sleeping in bedrooms with walls covered by paper containing arsenical pigment. Men employed in the grinding and mixing of such colours suffered from ulcers on their hands and fingers and upon the genitalia. In other instances a painful neuritis was established which occasionally ended in paralysis. In the United States, in Holland, and other countries the subject had also received attention. In Massachusetts, for example, a law had been passed in 1900 limiting the amount of arsenic in wall-paper to the extent of 0·1 gr. per square yard, but at the time of the British inquiry alluded to, we found manufacturers had been placing several grains in a square foot of wall-paper. The use of arsenical pigments in wall-paper in Great Britain was subsequently prohibited, their place being taken by aniline and other safe colours. To the fortunate results which have followed in all the trades wherein arsenical compounds are used, stringent regulations, improved ventilation, and the employment of means for the removal of dust have contributed.

As an illustration of the good effected I need only allude to the experience of Sir Thomas Legge who, in 1900, found in one of the London factories wherein "Paris green" was made, that 20 out of the 33 male workers employed therein had to be suspended—that is, 60 per cent.; but as a consequence of more stringent regulations, cleanliness, baths, &c., he found, 13 years afterwards, that the suspension from work were only 0·6 per cent.

Carbon Bisulphide.

Thirty years ago in the manufacture of india-rubber goods in Great Britain there was much serious illness among the men and women employed in the factories. The illness was traced to the use of carbon bisulphide as a solvent for sulphur monochloride in the vulcanisation of rubber. The vapour of bisulphide when inhaled causes intoxication not unlike that which follows the drinking to excess of alcoholic liquors. In the milder forms there are headache, vomiting, and a staggering gait; in the more pronounced form the symptoms, while primarily of the nature of aggravated hysteria, occasionally become those met with in acute mania; in other instances again there are indications of peripheral neuritis followed by paralysis of the limbs. Since new methods of vulcanising rubber by means of the incorporation of flowers of sulphur in a closed chamber under the influence of heat have been introduced, the trade has become healthier and there are no longer the distressing and crippling forms of illness which attacked the workers less than half a century ago.

Lead and Its Compounds.

If there is one metal more than others which since the rise of the modern industries has exacted in all manufacturing countries a high toll of human life it is lead and its compounds. One thing characteristic of industrial lead poisoning is the insidious manner in which it may develop; ill-health may gradually steal over the workers, or on the other hand, symptoms may rapidly show themselves, as, for example, by the sudden onset of acute abdominal pain, or loss of power in one or both hands, between night and morning. As lead and its compounds are used in over 130 industries, this circumstance renders lead one of the most important metals from an industrial point of view, just as, regarded medically, it is one of the most interesting. In Great Britain and in Western Europe lead is present in ore as galena or sulphide, and as this is rather insoluble in weak acid solutions, miners who blast the ore and are exposed to dust do not suffer from plumbism but from a dust disease of the lung called *silicosis*. In the Broken Hill Mines of Australia lead was present a generation ago in the form of *cerussite* or carbonate; this, when inhaled as fine dust, is readily soluble and becomes not only a source of plumbism but of the severer type of the malady known as saturnine encephalopathy. It was a fortunate circumstance for the owners of the Broken Hill Mines that after the cerussite layer had been worked out the subjacent ore was found to be galena, for the mining of this was followed by a marked declension in the number of cases of lead poisoning. A strange circumstance, however, has arisen at Broken Hill. Recently there has been a recrudescence of lead poisoning; this was found to be due to the lead ore in places having become changed into cerussite.

As regards lead, the dangers of industrial poisoning occurs during the smelting of the ore, the extraction of silver from the pig lead, plumbing and soldering, the manufacture of white and red lead, the mixing and use of paints, the use of lead compounds in the manufacture of pottery and of accumulators for electrical purposes, also in the dyeing of textile fabrics, &c. It is hardly likely, owing to fuller knowledge among the workers of the value of personal

Notes, Comments, and Abstracts.

SOME ACHIEVEMENTS OF INDUSTRIAL LEGISLATION AND HYGIENE.

Being an Address delivered to the Congress of Industrial Hygiene, Amsterdam, Sept. 12th, 1925,

By Sir Thomas Oliver, M.D. Glasg.,
PRESIDENT OF THE BRITISH SECTION.

Industrial hygiene is a comparatively recent branch of medicine. Although Ramazzini published his treatise on "Occupation Diseases" in 1700, it was the utilisation of steam as a motive power which stimulated the growth of modern industry. The manufacture of pottery, also of bricks for building purposes, is one of the oldest trades. Coal-mining, on the other hand, is one of the most important industries as it is one of the most dangerous. The Romans during their occupation of Great Britain made use of the coal obtained from "drifts" in the city and neighbourhood of Newcastle-upon-Tyne. There was no deep mining for coal in those days. It was in the early part of the thirteenth century that permission was granted by Henry II. to dig for coal in the North of England. During the early part of last century coal-mining in Great Britain was a procedure attended by great hardships, physical and social, upon those who followed the vocation. A hundred years ago the hours of work were long, 12 to 13 per day, boy labour was exploited, and female labour underground was utilised; there was only one shaft leading into the mine, which served both for men and material, and, as a consequence, not only was there no "through ventilation" of coal-mines, but in the event of the single shaft becoming blocked there were no means of escape for the men underground or their comrades above ground reaching them. It was the occurrence of such an accident at a pit a few miles from Newcastle, known as the Hartley Colliery Disaster, 60 years ago or thereabouts, which led to the compulsory provision of two shafts into a mine whereby there is the "through ventilation" which is in use to-day. The winning of coal has always been a hazardous occupation. It was therefore to be expected that the risks and dangers to life in coal-mining through accident and illness, also the long hours of work, would at the earliest opportunity engage the attention of the British Parliament.

Two months ago I was called professionally to see a retired coal-miner, aged 72, who told me that he began work in the mine at the age of 9; that he worked from 4 A.M. till 5 P.M., and for this 13 hours work per day he received 10*d.* He had to be wakened at 3 A.M., left the house at 3.30 A.M., and had to walk more than a mile to the mine where at the pithead he was obliged to be ready to descend at 4 o'clock in the morning. He often slept while he walked to and from his work, and like the boys younger than himself employed in the mine, he frequently fell asleep at his work, and for which he was ill-treated by the foreman. In the winter months collier boys never saw daylight except on Sunday. It is an interesting fact that as recently as the last decade of the eighteenth century, miners and salters—that is, men who obtained salt from sea-brine—were, practically speaking, serfs in Scotland. Those men could be bought and sold along with the purchase and sale of mines. It was not until 1799 that they received their freedom. The circumstance just mentioned may to some extent explain the deplorable conditions which prevailed in coal-mining in the early years of last century in Great Britain, also the unsatisfactory housing of coal-miners and their families.

Fatal Accidents.

It is impossible to say what the number of fatal accidents was three-quarters of a century ago, for statistics at that period were not kept, but the death-roll was heavy. Before 1814 it was not the custom for inquests to be held on colliers who met their death by an accident in the mine. As showing the death-rate from mine accidents during the latter half of 1800, the following data supplied to me by Prof. H. Louis, of the Mining Department, Armstrong College, are of interest. Taking quinquennial periods, the death-rates from mining accidents per 1000 men employed underground in Great Britain were :—

Year.		Year.	
1851–55	5·149	1876–80	2·709
1856–60	4·628	1881–85	2·312
1861–65	3·791	1886–90	2·042
1866–70	3·995	1891–95	1·704
1871–75	2·730	1896–99	1·479

If we take two later decennial periods for comparison, we find that the average annual deaths from accidents in British mines due to all causes were: 1873–82, per 1000 men employed 2·5, and from 1911–20 1·3.

With the exception of the United States of America the statistics of other countries also show a decline in the accident fatality-rates.[1] In Germany the rate, which was 3·18 per 1000 men employed in 1870, had fallen to 2·40 in 1914; in the United States the fatal accident-rate had risen from 3·5 per 1000 in 1890 to 3·62 in 1920, while during 1920 the rate for Belgium was 1·13, France 0·77, Great Britain 0·88, and 2·40 for Germany. Coal-mining in the United States is a comparatively modern industry; the men have not been so long trained as those in the older countries. In addition, many foreigners are employed and, as a consequence of difficulties incidental to language, orders given by officials may not be readily understood. The men, too, in order to make high wages work harder than in most countries. If the accident-rate is measured by the number of men killed for every million tons of coal raised, the figures for the United States compare most favourably with those of other countries.

Coal Mining.

Speaking generally for all countries, but especially for my own, the figures show that improvement has taken place in the reduction of fatal accidents in coal-mining, largely consequent upon freer ventilation, daily inspection of the mine for gas before the men descend, greater use of safety-lamps, substitution of the higher explosives for ordinary black gunpowder, also the employment of skilled men to place in situ the cartridges and fire them.

Although one of the most dangerous of occupations, coal-mining in Great Britain remained free from protective legislation until 1842, when owing to the serious condition of affairs revealed by a Royal Commission, women and girls were excluded from working underground. It was not, however, until 13 years afterwards that measures were introduced to protect the health, life, and limbs of the workers. For the saving of life in coal-mines we are indebted to the attention given to the subject by men engaged in chemical and physical research. The employment of the "safety-lamp" recommended by Sir Humphry Davy has prevented many explosions, just as the daily inspection by trained men of the areas at the working face of the mine before commencing to hew coal has been the means of saving many a miner from getting "gassed." One other important circumstance has added considerably to the safety of the miner's vocation. Three-quarters of a century ago the dangers of explosive gases in coal-mines had been recognised, but it was not until a few more decades had passed that Prof. Galloway and Mr. H. Hall showed that as widespread explosions frequently followed the firing of cartridges in mines, some of these explosions were due to the dry coal-dust which was raised into the atmosphere catching fire and travelling with explosive rapidity through the underground passages. Men were thus killed partly by gas, partly by burns, and in other instances, where death was not immediate, by pneumonia. Coal-mining on a large scale in France, Belgium, and Germany is of recent date compared with that of Great Britain. It was not, for example, until 1760 that coal-mining in Westphalia became a prominent industry. Other coal-producing countries have profited by the experience, the mistakes, and failures of British mining methods. As an illustration of how hygienic measures introduced to protect the workers in one direction may inadvertently lead to disaster in another, I cannot do better than reproduce the experience of the German mining authorities in the Ruhr a few years ago. Before the war several of the coal-mines in Central and Western Europe had become infected by ankylostomiasis. I visited the Belgian, German, and Hungarian coal-fields, and I descended into the Lothringen Mine near Bochum. I was much impressed by the excellent organisation, the sanitary measures which had been carefully prepared by Dr. Tenholt, and the adequate hospital provision made by the mine authorities for combating the disease in Westphalia. Although the parasite had gained entrance into the tin-mines of Cornwall, British coal-mines, fortunately, remained free. Ankylostoma ova and larvæ require heat and a considerable amount of moisture for their development. A few years previously to my visit to Westphalia there had occurred explosions in the German coal-mines for which high temperatures and the dry coal-dust were partly believed to be responsible. With the view of reducing such risks it was decided to introduce water-spraying into the mines. This, however, only caused fresh trouble, for the mines became infected by the ankylostoma parasite, which it was believed had been brought thither by Polish and Italian workmen, also probably by some of their own miners who during the summer months had worked in the brickfields

around Cologne and elsewhere. At any rate, in 1900 water-spraying of mines became general and the result was as follows:—

---

[1] Kober: Industrial Hygiene, p. 145.

Year.	Cases of ankylostomiasis.	Year.	Cases of ankylostomiasis.
1896	107	1899	275
1897	113	1901	1030
1898	99	1902	1355

The rapid and great increase in the number of cases of ankylostomiasis after water-spraying can hardly be regarded as a coincidence.

As a class, coal-miners suffer less from pulmonary tuberculosis than most men employed in dusty occupations, but as Prof. E. L. Collis[1] remarks, "low as their phthisis mortality is, the experience for coal-miners displays certain statistical characteristics which are distinctive of dust phthisis," and these are "(1) an unusually late age of maximum incidence, and (2) an association with high mortalities from other respiratory diseases." Miners who are working at the coal face suffer from phthisis rather more than other miners below ground and workers above ground. Phthisis in coal-miners commences to express itself at and after 35 years of age, as the following figures show:—

Periods.	Age periods—			
	35	45	55	65 and over.
1890–92	1·45	2·07	2·23	2·03
1900–02	1·09	1·52	2·04	1·47
1910–12	1·02	1·31	1·43	1·02

The above data show the improvement which has taken place in the mortality-rate of coal-miners from phthisis.

Manufacture of Lucifer Matches.

There must be many in this audience who like myself, 20 to 30 years ago, were witnesses of the ill-health experienced by men and women who worked in match factories wherein white phosphorus was used. The men who dipped the matches in the phosphorus paste and the women who filled the boxes frequently suffered from necrosis of the jaw-bones or died from septic meningitis or broncho-pneumonia. In other instances where the poisoning was less severe the workers suffered from gastric trouble, anæmia, and albuminuria, or from a tendency of the long bones to become fractured owing to peculiar fragility. So great was the suffering of the persons who became affected that it became imperative that some united action should be taken by various Governments to produce matches which would strike anywhere without the workers incurring risk to their health. As far back as 1870 Switzerland introduced a Bill to prohibit the use of white phosphorus. In 1899 the British Government invited Sir Edward Thorpe, Dr. Cunningham, and myself to visit match works at home and abroad with the view of ascertaining how the workers might be protected against the risks they were exposed to. Like many of our Continental confrères, we were of the opinion that the time had come when a harmless substitute should be found for the dangerous white phosphorus. It was Lorinser, of Vienna, who in 1845 first drew attention to necrosis of the jaw-bones as an occupational disease, but in every country in which lucifer matches had been made from white phosphorus there had occurred cases of "phossy jaw." Chemists vied with each other to find a safe substitute for the dangerous metalloid. To French scientists fell the honour of showing how by employing sesquisulphide of phosphorus lucifer matches could be made without risk to the health of the workers. After a congress of the various Governments held in Berne in 1906, the match-producing countries of Western Europe decided to manufacture lucifers by the safe method, and so successful has been the result that the occupation is now free from the risks of three decades ago. Phosphorus necrosis has disappeared. This is one of the triumphs of industrial hygiene of which chemistry and medicine may well be proud and for which we are indebted to France.

Manufacture of Mirrors.

Chemical research has also proved helpful in other trades. It is not so long ago since quicksilver was used in the manufacture of mirrors. Many of the men then employed suffered from mercurial poisoning. Apart from the unhealthy conditions set up in the mouth through vaporisation of quicksilver, the workers became the victims of muscular tremor and occasionally of paralysis. Since making use of nitrate of silver preparations the men have had good health and the industry is now regarded as a healthy one.

Arsenical Pigments.

Just over 20 years ago I was a member of the Dangerous Trades' Committee of the Home Office to whom was given the task of investigating several trades which were regarded as inimical to health. One of these was the manufacture and use of wall-papers which contained arsenic, also the manufacture, mixing, and use of "emerald green." It had been found that much illness hitherto unrecognised was the result of sleeping in bedrooms with walls covered by paper containing arsenical pigment. Men employed in the grinding and mixing of such colours suffered from ulcers on their hands and fingers and upon the genitalia. In other instances a painful neuritis was established which occasionally ended in paralysis. In the United States, in Holland, and other countries the subject had also received attention. In Massachusetts, for example, a law had been passed in 1900 limiting the amount of arsenic in wall-paper to the extent of 0·1 gr. per square yard, but at the time of the British inquiry alluded to, we found manufacturers had been placing several grains in a square foot of wall-paper. The use of arsenical pigments in wall-paper in Great Britain was subsequently prohibited, their place being taken by aniline and other safe colours. To the fortunate results which have followed in all the trades wherein arsenical compounds are used, stringent regulations, improved ventilation, and the employment of means for the removal of dust have contributed.

SOME ACHIEVEMENTS OF INDUSTRIAL LEGISLATION AND HYGIENE.

Being an Address delivered to the Congress of Industrial Hygiene, Amsterdam, Sept. 12th, 1925,

BY SIR THOMAS OLIVER, M.D. GLASG.,
PRESIDENT OF THE BRITISH SECTION.

INDUSTRIAL hygiene is a comparatively recent branch of medicine. Although Ramazzini published his treatise on "Occupation Diseases" in 1700, it was the utilisation of steam as a motive power which stimulated the growth of modern industry. The manufacture of pottery, also of bricks for building purposes, is one of the oldest trades. Coal-mining, on the other hand, is one of the most important industries as it is one of the most dangerous. The Romans during their occupation of Great Britain made use of the coal obtained from "drifts" in the city and neighbourhood of Newcastle-upon-Tyne. There was no deep mining for coal in those days. It was in the early part of the thirteenth century that permission was granted by Henry II. to dig for coal in the North of England. During the early part of last century coal-mining in Great Britain was a procedure attended by great hardships, physical and social, upon those who followed the vocation. A hundred years ago the hours of work were long, 12 to 13 per day, boy labour was exploited, and female labour underground was utilised; there was only one shaft leading into the mine, which served both for men and material, and, as a consequence, not only was there no "through ventilation" of coal-mines, but in the event of the single shaft becoming blocked there were no means of escape for the men underground or their comrades above ground reaching them. It was the occurrence of such an accident at a pit a few miles from Newcastle, known as the Hartley Colliery Disaster, 60 years ago or thereabouts, which led to the compulsory provision of two shafts into a mine whereby there is the "through ventilation" which is in use to-day. The winning of coal has always been a hazardous occupation. It was therefore to be expected that the risks and dangers to life in coal-mining through accident and illness, also the long hours of work, would at the earliest opportunity engage the attention of the British Parliament.

Two months ago I was called professionally to see a retired coal-miner, aged 72, who told me that he began work in the mine at the age of 9; that he worked from 4 A.M. till 5 P.M., and for this 13 hours work per day he received 10*d.* He had to be wakened at 3 A.M., left the house at 3.30 A.M., and had to walk more than a mile to the mine where at the pithead he was obliged to be ready to descend at 4 o'clock in the morning. He often slept while he walked to and from his work, and like the boys younger than himself employed in the mine, he frequently fell asleep at his work, and for which he was ill-treated by the foreman. In the winter months collier boys never saw daylight except on Sunday. It is an interesting fact that as recently as the last decade of the eighteenth century, miners and salters—that is, men who obtained salt from sea-brine—were, practically speaking, serfs in Scotland. Those men could be bought and sold along with the purchase and sale of mines. It was not until 1799 that they received their freedom. The circumstance just mentioned may to some extent explain the deplorable conditions which prevailed in coal-mining in the early years of last century in Great Britain, also the unsatisfactory housing of coal-miners and their families.

Fatal Accidents.

It is impossible to say what the number of fatal accidents was three-quarters of a century ago, for statistics at that period were not kept, but the death-roll was heavy. Before 1814 it was not the custom for inquests to be held on colliers who met their death by an accident in the mine. As showing the death-rate from mine accidents during the latter half of 1800, the following data supplied to me by Prof. H. Louis, of the Mining Department, Armstrong College, are of interest. Taking quinquennial periods, the death-rates from mining accidents per 1000 men employed underground in Great Britain were:—

Year.		Year.	
1851–55	5·149	1876–80	2·709
1856–60	4·628	1881–85	2·312
1861–65	3·791	1886–90	2·042
1866–70	3·995	1891–95	1·704
1871–75	2·736	1896–99	1·479

If we take two later decennial periods for comparison, we find that the average annual deaths from accidents in British mines due to all causes were: 1873–82, per 1000 men employed 2·5, and from 1911–20 1·3.

With the exception of the United States of America the statistics of other countries also show a decline in the accident fatality-rates.[1] In Germany the rate, which was 3·18 per 1000 men employed in 1879, had fallen to 2·40 in 1914; in the United States the fatal accident-rate had risen from 3·5 per 1000 in 1890 to 3·62 in 1920, while during 1920 the rate for Belgium was 1·13, France 0·77, Great Britain 0·88, and 2·40 for Germany. Coal-mining in the United States is a comparatively modern industry; the men have not been so long trained as those in the older countries. In addition, many foreigners are employed and, as a consequence of difficulties incidental to language, orders given by officials may not be readily understood. The men, too, in order to make high wages work harder than in most countries. If the accident-rate is measured by the number of men killed for every million tons of coal raised, the figures for the United States compare most favourably with those of other countries.

Coal Mining.

Speaking generally for all countries, but especially for my own, the figures show that improvement has taken place in the reduction of fatal accidents in coal-mining, largely consequent upon freer ventilation, daily inspection of the mine for gas before the men descend, greater use of safety-lamps, substitution of the higher explosives for ordinary black gunpowder, also the employment of skilled men to place *in situ* the cartridges and fire them.

Although one of the most dangerous of occupations, coal-mining in Great Britain remained free from protective legislation until 1842, when owing to the serious condition of affairs revealed by a Royal Commission, women and girls were excluded from working underground. It was not, however, until 13 years afterwards that measures were introduced to protect the health, life, and limbs of the workers. For the saving of life in coal-mines we are indebted to the attention given to the subject by men engaged in chemical and physical research. The employment of the "safety-lamp" recommended by Sir Humphry Davy has prevented many explosions, just as the daily inspection by trained men of the areas at the working face of the mine before commencing to hew coal has been the means of saving many a miner from getting "gassed." One other important circumstance has added considerably to the safety of the miner's vocation. Three-quarters of a century ago the dangers of explosive gases in coal-mines had been recognised, but it was not until a few more decades had passed that Prof. Galloway and Mr. H. Hall showed that as widespread explosions frequently followed the firing of cartridges in mines, some of these explosions were due to the dry coal-dust which was raised into the atmosphere catching fire and travelling with explosive rapidity through the underground passages. Men were thus killed partly by gas, partly by burns, and in other instances, where death was not immediate, by pneumonia. Coal-mining on a large scale in France, Belgium, and Germany is of recent date compared with that of Great Britain. It was not, for example, until 1766 that coal-mining in Westphalia became a prominent industry. Other coal-producing countries have profited by the experience, the mistakes, and failures of British mining methods. As an illustration of how hygienic measures introduced to protect the workers in one direction may inadvertently lead to disaster in another, I cannot do better than reproduce the experience of the German mining authorities in the Ruhr a few years ago. Before the war several of the coal-mines in Central and Western Europe had become infected by ankylostomiasis. I visited the Belgian, German, and Hungarian coal-fields, and I descended into the Lothringen Mine near Bochum. I was much impressed by the excellent organisation, the sanitary measures which had been carefully prepared by Dr. Tenholt, and the adequate hospital provision made by the mine authorities for combating the disease in Westphalia. Although the parasite had gained entrance into the tin-mines of Cornwall, British coal-mines, fortunately, remained free. Ankylostoma ova and larvæ require heat and a considerable amount of moisture for their development. A few years previously to my visit to Westphalia there had occurred explosions in the German coal-mines for which high temperatures and the dry coal-dust were partly believed to be responsible. With the view of reducing such risks it was decided to introduce water-spraying into the mines. This, however, only caused fresh trouble, for the mines became infected by the ankylostoma parasite, which it was believed had been brought thither by Polish and Italian workmen, also probably by some of their own miners who during the summer months had worked in the brickfields

around Cologne and elsewhere. At any rate, in 1900 water-spraying of mines became general and the result was as follows:—

---

[1] Kober: Industrial Hygiene, p. 145.

Year.	Cases of ankylostomiasis.	Year.	Cases of ankylostomiasis.
1896	107	1899	276
1897	113	1901	1030
1898	90	1903	1355

The rapid and great increase in the number of cases of ankylostomiasis after water-spraying can hardly be regarded as a coincidence.

As a class, coal-miners suffer less from pulmonary tuberculosis than most men employed in dusty occupations, but as Prof. E. L. Collis[2] remarks, "low as their phthisis mortality is, the experience for coal-miners displays certain statistical characteristics which are distinctive of dust phthisis," and these are "(1) an unusually late age of maximum incidence, and (2) an association with high mortalities from other respiratory diseases." Miners who are working at the coal face suffer from phthisis rather more than other miners below ground and workers above ground. Phthisis in coal-miners commences to express itself at and after 35 years of age, as the following figures show:—

Periods.	Age periods—			
	35	45	55	65 and over.
1890–92	1·45	2·07	2·23	2·03
1900–02	1·00	1·52	2·04	1·47
1910–12	1·02	1·31	1·43	1·02

The above data show the improvement which has taken place in the mortality-rate of coal-miners from phthisis.

Manufacture of Lucifer Matches.

There must be many in this audience who like myself, 20 to 30 years ago, were witnesses of the ill-health experienced by men and women who worked in match factories wherein white phosphorus was used. The men who dipped the matches in the phosphorus paste and the women who filled the boxes frequently suffered from necrosis of the jaw-bones or died from septic meningitis or broncho-pneumonia. In other instances where the poisoning was less severe the workers suffered from gastric trouble, anæmia, and albuminuria, or from a tendency of the long bones to become fractured owing to peculiar fragility. So great was the suffering of the persons who became affected that it became imperative that some united action should be taken by various Governments to produce matches which would strike anywhere without the workers incurring risk to their health. As far back as 1870 Switzerland introduced a Bill to prohibit the use of white phosphorus. In 1890 the British Government invited Sir Edward Thorpe, Dr. Cunningham, and myself to visit match works at home and abroad with the view of ascertaining how the workers might be protected against the risks they were exposed to. Like many of our Continental confrères, we were of the opinion that the time had come when a harmless substitute should be found for the dangerous white phosphorus. It was Lorinser, of Vienna, who in 1845 first drew attention to necrosis of the jaw-bones as an occupational disease, but in every country in which lucifer matches had been made from white phosphorus there had occurred cases of "phossy jaw." Chemists vied with each other to find a safe substitute for the dangerous metalloid. To French scientists fell the honour of showing how by employing sesquisulphide of phosphorus lucifer matches could be made without risk to the health of the workers. After a congress of the various Governments held in Berne in 1906, the match-producing countries of Western Europe decided to manufacture lucifers by the safe method, and so successful has been the result that the occupation is now free from the risks of three decades ago. Phosphorus necrosis has disappeared. This is one of the triumphs of industrial hygiene of which chemistry and medicine may well be proud and for which we are indebted to France.

Manufacture of Mirrors.

Chemical research has also proved helpful in other trades. It is not so long ago since quicksilver was used in the manufacture of mirrors. Many of the men then employed suffered from mercurial poisoning. Apart from the unhealthy conditions set up in the mouth through vaporisation of quicksilver, the workers became the victims of muscular tremor and occasionally of paralysis. Since making use of nitrate of silver preparations the men have had good health and the industry is now regarded as a healthy one.

Arsenical Pigments.

Just over 20 years ago I was a member of the Dangerous Trades' Committee of the Home Office to whom was given the task of investigating several trades which were regarded as inimical to health. One of these was the manufacture and use of wall-papers which contained arsenic, also the manufacture, mixing, and use of "emerald green." It had been found that much illness hitherto unrecognised was the result of sleeping in bedrooms with walls covered by paper containing arsenical pigment. Men employed in the grinding and mixing of such colours suffered from ulcers on their hands and fingers and upon the genitalia. In other instances a painful neuritis was established which occasionally ended in paralysis. In the United States, in Holland, and other countries the subject had also received attention. In Massachusetts, for example, a law had been passed in 1900 limiting the amount of arsenic in wall-paper to the extent of 0·1 gr. per square yard, but at the time of the British inquiry alluded to, we found manufacturers had been placing several grains in a square foot of wall-paper. The use of arsenical pigments in wall-paper in Great Britain was subsequently prohibited, their place being taken by aniline and other safe colours. To the fortunate results which have followed in all the trades wherein arsenical compounds are used, stringent regulations, improved ventilation, and the employment of means for the removal of dust have contributed.

As an illustration of the good effected I need only allude to the experience of Sir Thomas Legge who, in 1900, found in one of the London factories wherein "Paris green" was made, that 20 out of the 33 male workers employed therein had to be suspended—that is, 60 per cent.; but as a consequence of more stringent regulations, cleanliness, baths, &c., he found, 13 years afterwards, that the suspension from work were only 0·6 per cent.

Carbon Bisulphide.

Thirty years ago in the manufacture of india-rubber goods in Great Britain there was much serious illness among the men and women employed in the factories. The illness was traced to the use of carbon bisulphide as a solvent for sulphur monochloride in the vulcanisation of rubber. The vapour of bisulphide when inhaled causes intoxication not unlike that which follows the drinking to excess of alcoholic liquors. In the milder forms there are headache, vomiting, and a staggering gait; in the more pronounced form the symptoms, while primarily of the nature of aggravated hysteria, occasionally become those met with in acute mania; in other instances again there are indications of peripheral neuritis followed by paralysis of the limbs. Since new methods of vulcanising rubber by means of the incorporation of flowers of sulphur in a closed chamber under the influence of heat have been introduced, the trade has become healthier and there are no longer the distressing and crippling forms of illness which attacked the workers less than half a century ago.

Lead and Its Compounds.

If there is one metal more than others which since the rise of the modern industries has exacted in all manufacturing countries a high toll of human life it is lead and its compounds. One thing characteristic of industrial lead poisoning is the insidious manner in which it may develop; ill-health may gradually steal over the workers, or on the other hand, symptoms may rapidly show themselves, as, for example, by the sudden onset of acute abdominal pain, or loss of power in one or both hands, between night and morning. As lead and its compounds are used in over 130 industries, this circumstance renders lead one of the most important metals from an industrial point of view, just as, regarded medically, it is one of the most interesting. In Great Britain and in Western Europe lead is present in ore as galena or sulphide, and as this is rather insoluble in weak acid solutions, miners who blast the ore and are exposed to dust do not suffer from plumbism but from a dust disease of the lung called *silicosis*. In the Broken Hill Mines of Australia lead was present a generation ago in the form of *cerussite* or carbonate; this, when inhaled as fine dust, is readily soluble and becomes not only a source of plumbism but of the severer type of the malady known as saturnine encephalopathy. It was a fortunate circumstance for the owners of the Broken Hill Mines that after the cerussite layer had been worked out the subjacent ore was found to be galena, for the mining of this was followed by a marked declension in the number of cases of lead poisoning. A strange circumstance, however, has arisen at Broken Hill. Recently there has been a recrudescence of lead poisoning; this was found to be due to the lead ore in places having become changed into cerussite.

As regards lead, the dangers of industrial poisoning occurs during the smelting of the ore, the extraction of silver from the pig lead, plumbing and soldering, the manufacture of white and red lead, the mixing and use of paints, the use of lead compounds in the manufacture of pottery and of accumulators for electrical purposes, also in the dyeing of textile fabrics, &c. It is hardly likely, owing to fuller knowledge among the workers of the value of personal the shape shown in Fig. 0 with two D-shaped openings facing each other. Make a cut midway between the two D's and then pass a strip of bandage through the two openings and tie it at their lower part. This kinks the apparatus and makes it concave. In this case ordinary instead of corrugated cardboard is better.

---

[2] Journal of Industrial Hygiene, May, 1925, p. 228.

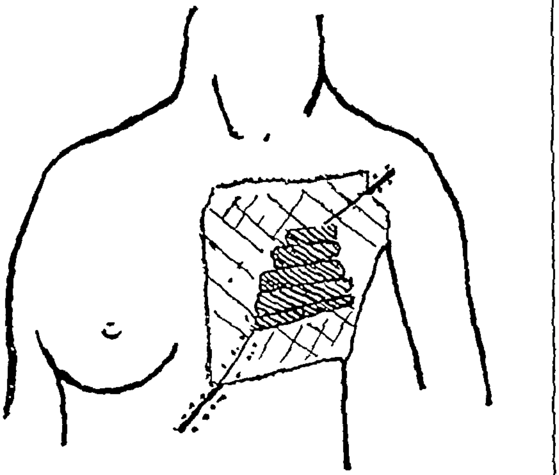
4. *On a Nutrient Beef-tea.*

Although milk is so nearly perfect as a fluid food, it is often desirable to have an alternative albuminous fluid food, for example, for patients who dislike milk.

Pound 2 oz. of fillet of beef in a mortar with 1 oz. of cold water, press the resulting paste through a wire sieve with the back of a wooden spoon or a vegetable presser. Return what comes through the sieve to the mortar. Pour into the mortar on top of the pounded meat 6 oz. of boiling bouillon, clear soup, or if nothing better is available, one of the commercial meat extracts. Stir this up and then pass it again through the sieve, which still has some particles of meat entangled in its meshes, which particles get washed through with the broth. The result is a reddish fluid which sets into a jelly after a few hours, and should measure about 8 or 9 oz.; that is to say, the whole of the 2 oz. of fillet of beef are contained in a tumblerful of liquid. The meat is very lightly cooked, but if the bouillon is skilfully prepared there is no raw taste. Other kinds of beef can be used, but they are inferior to fillet, as they contain more fat and fibrous tissue.

I have given this formula to Messrs. Withers, of 20a, Baker-street, who are prepared to supply this beef-tea to order, and as prepared by them it is an extremely palatable product. I have examined it microscopically and find that the beef is reduced practically to its ultimate fibres, and that many of these are actually broken up. Needless to say, this preparation will not keep and must therefore be freshly prepared daily.

FIG. 3.



A method of keeping Thiersch grafts in position.

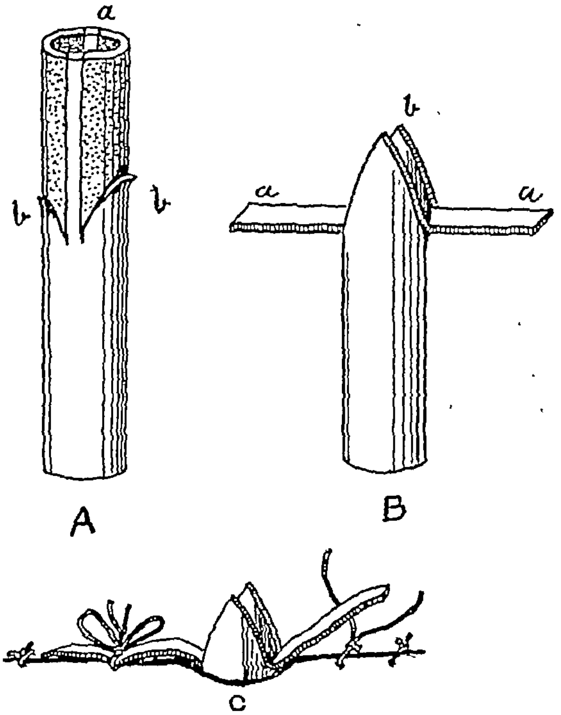
5. *On Keeping Thiersch Grafts in Position.*

In Fig. 3 the condition is represented in which the left breast of a patient has been removed for carcinoma and it has been found impossible to bring the skin together. The darkly shaded portion represents the skin grafts which have been applied subsequently. After this has been done a piece of sterilised mosquito-netting is gently laid over the grafts, stretched out flat on the chest wall and fixed in position with collodion all round the wound. The collodion is not painted on to the grafts, but merely on the skin around them, the tension of the netting serving to hold the grafts down. Over this any dressings that the surgeon may fancy can be applied. If there is much discharge this will escape through the mesh of the netting, and it will be found possible to renew the dressing without disturbing the grafts.

6. *On the Insertion of Drainage-tubes.*

It is important where a drainage-tube is to be inserted through a stab wound to see that the lines of the stab correspond with the lines of the cleavage of the skin or with the lines of tension of a flap. For example, after total amputation of the breast, if a drainage-tube is put in through a stab wound in the long axis of the body the hole will be dragged open and take a long time to heal. If, on the other hand, the incision for the drainage-tube is at right angles to the trunk the tension of the flap will tend to close it and it will heal rapidly. In putting a drainage-tube into the centre of an incision, for example after an operation for goitre, it is important to see that the edges of the incision lie evenly around the tube. The best way to do this is to put two sutures in the middle of the incision sufficiently far apart to admit the drainage-tube and so placed that there is exactly the same amount of skin above and below the incision. When the tube is removed the two edges fall together naturally, whereas if one had been a little longer than the other there would have been an ugly scar. After removing a tube, one sometimes desires to press the part to find out if there is any collection of pus within it. In the case of wounds of certain parts, for example of the neck, this can often be done by holding a swab against the wound and directing the patient to do the pressing for himself. Nervous patients appreciate this.

FIG. 4.

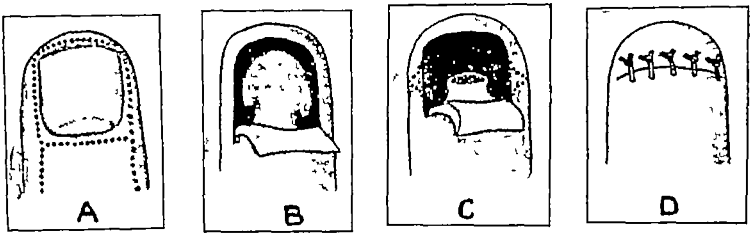


A drainage-tube for empyema.

7. *On a Drainage-tube for Empyema.*

This is a slight modification of a device which I have already published. The drainage-tube of the desired length and size is cut as in Fig. 4, A, two oblique cuts mark out the angular flaps (*b*), and the ends of these two cuts are joined to the open end of the tube by two pairs of cuts, marking out the two long narrow flaps (*a*), the dotted part coming away, leaving a tube as shown opened out in B. The tube is put into position and a stitch passed through the edges of the wound on either side, its ends being tied and left long. These long ends are then tied round the long flaps (*a*) holding the tube firmly in position. The triangular flaps hold the edges of the wound aside and prevent them from falling over the end of the tube. To remove the tube the bows are untied, the tube washed, replaced, and the bows retied (C). The sutures hold for a week or ten days, at the end of which it is usually easier to retain a tube of the ordinary pattern.

FIG. 5.

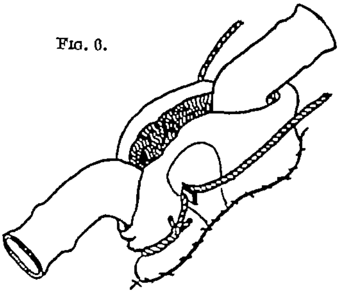


A method of removing finger- and toe-nails.

8. *On Removing Finger- and Toe-nails.*

The operation of removing a nail is usually called "avulsion," a term which suggests violence. The best way to do this little operation is to use a thin flat-bladed blunt dissector; the one sold under the name of MacDonald's raspatory is an excellent one. This is gently insinuated under the nail and moved from side to side so as to gradually separate the nail from its bed. The nail can then be lifted up and removed with a minimum of laceration of the underlying structures, and, consequently, a more rapid and less painful healing. The operation takes a little longer; but as the patient is, or should be, always under an anæsthetic this is of no importance.

FIG. 6.



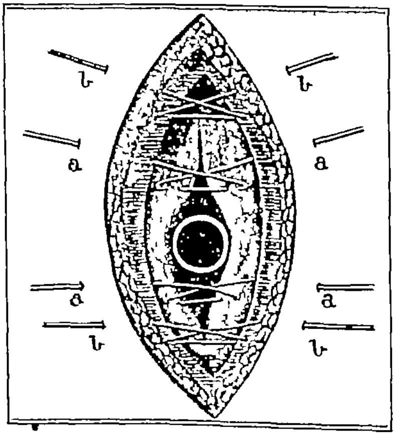
Showing the colotomy tubes in position.

In some cases, for example when the nail of the great toe is enormously overgrown, it is necessary to remove it completely, matrix-bed and all. The method illustrated in Fig. 5 will be found useful. The incisions are made as in A, surrounding the nail and running up on the phalanx for about half an inch. The little flap over the nail-bed is then dissected up and the nail-bed matrix and nail excised, leaving the terminal phalanx covered with a little fibrous tissue at the bottom of the wound as shown in B. The expanded end of the terminal phalanx is then cut off with a pair of bone forceps, leaving the condition shown in C. It is now quite a simple matter to sew up the whole wound completely as in D, leaving, when healing is complete, a painless rounded stump well calculated to bear pressure. Sometimes two little ear-like processes will be formed on either side of the incision. These can be removed by excising two little triangular flaps of skin as indicated by the dotted line in C. If the reflected flap over the matrix should prove to be too thin at its edge, this can be trimmed away.

9. *On Inguinal Colotomy.*

I practically always open the bowel in this operation immediately after fixing it in the wound. I carefully suture the bowel and the intervening mesentery to the skin with fine catgut and then pass two stout silk ligatures through the mesentery without interlocking them. I then pack round the bowel with gauze wet in 1 in 2000 perchloride of mercury to protect the wound. I next slit open the bowel, as shown in Fig. 6, clean it out, and pass a colotomy tube into each end. I then tie the two sutures one round each of the colotomy tubes and the bowel as tightly as possible, so as to hold them in position and completely avascularise the tissue beyond the ligature. As my hands are now soiled I remove my gloves, take away the wet gauze, and replace it by a cyanide gauze dressing wrung out of 1 in 40 carbolic acid. Colotomy

[FIG. 7.



Suturing of bladder and abdominal wall after prostatectomy.

tubes of india-rubber are tied over the glass tubes in the usual way. At the end of a week both tubes and the intervening piece of bowel separate cleanly without any hæmorrhage and a very satisfactory colotomy is obtained.

10. *On the Use of Figure-of-8 Suture after Prostatectomy.*

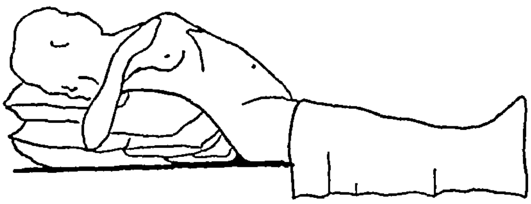
After removing the prostate I am in the habit of closing the wound around the drainage-tube as follows. *A stout silkworm-gut stitch is passed through the* muscular wall of the bladder on either side of the incision, avoiding the mucous membrane (Fig. 7 (*a*)). This is done above and below the tube, and the cut edges of the bladder are inverted around the tube. The sutures are then crossed and passed through the whole thickness of the abdominal wall—that which came from the right side of the incision into the bladder coming out on the left side of the incision in the skin and vice versa, so that when these are tightened up the bladder incision is turned in and the whole of the abdominal wound is approximated. But more superficial figure-of-8 sutures, as many as may be necessary, are put through the sheath of the rectus, crossed, and passed out through the skin (Fig. 7 (*b*)). When all these are tightened the abdominal wall is held well together, the edges of the bladder incision are inverted, and the bladder held well against the deep surface of the wound. These sutures are cut on the thirteenth day and removed on the fourteenth, thus leaving no buried sutures to cause trouble.

SOME PRACTICAL POINTS ON THE OPERATIVE SURGERY OF THE GALL-BLADDER.

1. In order to bring the biliary passages into a more accessible position, it is usual by some means or other to extend the spine into an arch, the summit of which is at the lower dorsal vertebræ. This may be done either by placing a firm. sandbag or a pneumatic pillow behind the patient in the lower dorsal region, by a "bridge" on the operating table, or by using a specially arranged operating table. All these positions are extremely uncomfortable to a conscious patient and are therefore a factor in producing discomfort after the operation. The method I have employed obtains exactly the same angulation of the spine in the lower dorsal region, but with much greater comfort. It is shown in Fig. 8.

After the patient has been laid upon the table he is lifted up almost into a sitting position, and firm pillows or sandbags are pushed tightly up against the lower part of the spine and banked up as far as the lower dorsal region. The patient's head and shoulders are then allowed to fall back to the horizontal position and supported by further pillows. In all, about half a dozen are required. It will be noticed that not only is the angulation secured but that the abdomen is acutely inclined, making an angle of about 45° with the horizontal, so that on opening the abdomen the small intestines drop away to the pelvis and do not intrude upon the field of operation. It is only necessary to persuade a few normal, conscious individuals to try this position and compare it with the older ones to demonstrate how much more comfortable it is. Further, anæsthetists tell me it is a better position from their point of view, as it interferes less with the freedom of respiration. I have used this method now for a long time and have found that it gives good access with all the various incisions for exposure of the gall-bladder. I may mention, in passing, that, like many surgeons, I now usually attack this region through a paramedian incision.

FIG. 8.



Position of patient on the operating table.

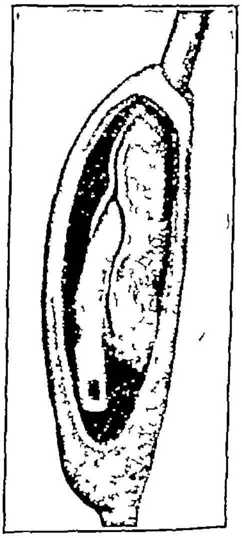
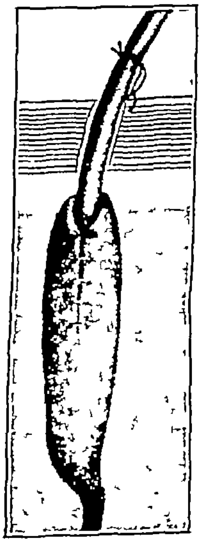
Incision into the gall-bladder with drainage-tube sutured to its margin.

FIG. 12.



Schematic view of the inside of gall-bladder as it would appear if viewed from the hepatic surface.

FIG. 13.

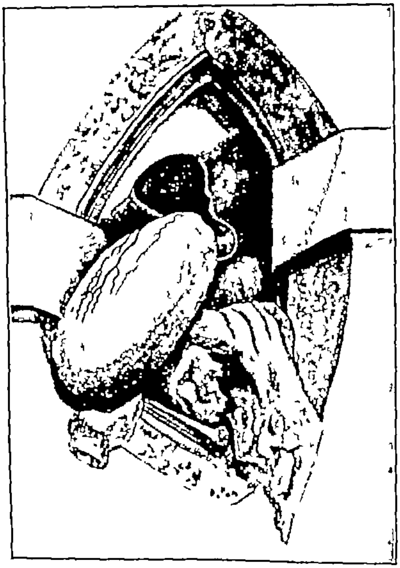


The drainage-tube in its final position.

2. In view of the accidents which have happened to the common duct in excising the gall-bladder, it is taught in most text-books that the dissection should commence over the cystic duct. In a thin patient, with a small gall-bladder, with lax hepatic ligaments, and a broad subcostal arch, this procedure is as easy as it appears to be in the illustrations in the

books on operative surgery. Unfortunately, however, a very large number of these cases are extremely fat, the gall-bladder is enlarged, obscuring the ducts, so that this method is difficult; and in such cases, even when it is possible, it can only be done by using a good deal of undesirable force. It is recommended in such cases that the gall-bladder should be aspirated before removal. In some cases this is, in my opinion, very undesirable and also unnecessary. The statement is made that it is almost impossible to remove the gall-bladder by commencing the separation from the liver at its fundus and at the same time to see distinctly the structures which are ligatured in the neighbourhood of the foramen of Winslow.

FIG. 10.



The separation of the gall bladder completed.

In such cases it is generally fairly easy, by incising the peritoneum, to separate the gall-bladder from the liver (Fig 9), starting at the fundus, care being taken, of course, to carry out the dissection at the proper level, and avoid lacerating the liver or the gall-bladder. The liver can now be held up by a retractor and a gauze pad packed over the raw area of the liver to control the hæmorrhage, if this is sufficient not to interfere with the operation. As a matter of fact, it is very rare that this is the case. The fundus of the gall-bladder is grasped, either with a piece of gauze or, if it is sufficiently lax, with a pair of ring forceps, and drawn downwards towards the right iliac fossa (Fig. 10). The incision between the liver and gall-bladder is then extended through the peritoneum from the lowest point on one side, transversely to the long axis of the gall-bladder until it meets the incision on the other side. It is immaterial whether this transverse part of the incision lies over the duct or over the lower part of the gall-bladder itself. This division of the peritoneum is quite easily carried out, provided that the peritoneum is drawn taut and a sharp knife is used. With a little blunt dissection it is now quite easy to push down the peritoneum between the transverse incision and the common duct. The gall-bladder is now connected only by its duct and its blood-vessels with a small amount of areolar tissue between. The cystic duct is separated from the remainder of the pedicle and traced downward as far as the surgeon thinks desirable. An aneurysm needle is passed around the remainder of the pedicle—that is to say, around the vessels, which are ligatured and divided—care being taken to leave a sufficient amount of tissue on the far side of the ligature to prevent it slipping off. The gall-bladder is left connected merely by the cystic duct which is ligatured and divided in the usual way. If the common bile-duct has not been exposed before, it is easy at this stage to do so, making gentle traction on the cystic duct and pushing the divided peritoneum aside.

To separate the gall-bladder from the liver, starting from the fundus and then to tie a string more or less blindly around a pedicle is certainly a dangerous procedure; but by this method we gain the advantage of a mobile gall-bladder and at the same time one can see exactly what is being ligatured Even when the transverse incision is made across the lower part of the gall-bladder it is usually quite easy to expose the whole of the cystic duct. Furthermore, if one has the consciousness that the duct has been well and truly ligatured a small escape of bile along the drainage-tube for the first 24 or 48 hours does not give the surgeon any apprehension that his ligature has slipped, as it will be evident that this escape is merely due to the lacerated bile-ducts on the surface of the liver.

3. Drainage of the gall-bladder is an operation less frequently performed to-day than formerly, but there are certain cases in which it is necessary. Some surgeons recommend the suture of the wall of the gall-bladder to the deeper part of the abdominal wall, while others recommend that a tube should be inserted and fastened in with a purse-string, the object of the purse-string being to invert the walls of the gall-bladder as the walls of the stomach are invaginated in a Kader's gastrostomy, so that when the tube is removed the gall-bladder will close rapidly.

Bickham recommends that when the incision into the gall-bladder is slit-like a few points of Lembert's sutures should be inserted and the drainage-tube brought out at the middle of the incision. The purse string method is very easily applicable when the gall-bladder is distended and has lax walls, but it is difficult to carry out in a contracted gall-bladder with thickened walls, especially if a large opening has been made in the gall-bladder in order that the surgeon may explore its interior with his finger, a procedure which, as Rutherford Morison says, should always be carried out. It is a good plan not to incise the gall-bladder actually at its fundus, but starting at a point about half an inch from its attachment to the liver, to carry the incision upwards as far as may be necessary to insert the finger, remove the stones, and clear the ducts (Fig 11) A drainage-tube about the size of a No. 12 catheter with several holes cut in its side is then pushed along the gall bladder towards the cystic duct and a non-absorbable suture passed through the gall bladder and tube. This suture is tied as tightly as possible, so that it will, in the course of a few days, cut through the tissues of the gall-bladder and liberate the tube, with which it ultimately comes away. The incision in the gall-bladder is then closed by several layers of Lembert's sutures, as many rows being inserted as possible, care being taken to tuck in the edges of gall-bladder between the tube and the liver The greater the amount of enfolding the more certainly will the gall-bladder fall together when the tube is removed and the less risk is there of the formation of a biliary fistula (Fig 12). The latter figure is a schematic diagram of the incision so sutured, viewed from within.

It is my experience that the discharge of bile in these cases ceases in 24 hours. The drainage-tube leading from the gall-bladder is brought out through the abdominal wall at a convenient point and fastened in position. To do this a silkworm-gut suture is passed through the skin and tied securely, but not too tightly. The loose ends are again tied together in a reef knot about half an inch from the skin, and the ends are now tied firmly round the drainage-tube (Fig. 13). The drainage-tube can be held very firmly in this way and it will take an appreciable tug to pull it out. Furthermore, by securing the drainage-tube in this way the lumen of the tube is not opened and the bile does not leak into the dressing, but runs away into the receptacle provided for it.

INSTRUCTION OF STUDENTS.

In order to make diagrams at the bedside I have had made for me sketch blocks of "poster paper" upon which I draw either with a carbon pencil or a "BB" carpenter's pencil, as sold by Winsor and Newton. To demonstrate cutaneous sutures I use spongiopiline. This is a sort of felt on one side of which is a black waterproof layer which represents the cuticle very well. If this is pinned on a blackboard incisions can be made into it and sewn up with thick white silk for class demonstrations. To illustrate plastic operations I use stockinette dress material, which is fastened loosely with drawing pins over a frame. Lines can be drawn on this with soft chalk, and sliding flap and other plastic operations can be readily carried out. The best material for the sutures is the thick real silk which is sold for knitting purposes. For demonstrating intestinal operations I employ a tube made of two thicknesses of flannel—the inside red flannel and the outside white flannel. With this all the ordinary methods of intestinal anastomosis can be quite readily demonstrated.

A CLINICAL STUDY OF DIABETIC COMA.*

BY W. W. PAYNE, M.B., B.S. LOND.,
PARSON RESEARCH FELLOW;
AND
E. P. POULTON, M.D. OXF., F.R.C.P. LOND.,
PHYSICIAN TO GUY'S HOSPITAL.
(*From the Medical Wards and the Laboratory of Clinical Chemistry, Guy's Hospital.*)

THE following 11 cases are recorded as illustrating some aspects of this complication which are worthy of note, and have a bearing on its present-day treatment.

CASE 1.—P. M., aged 25, male. Admitted under the care of Dr. A. P. Beddard. No history of illness till three weeks before admission. A sore-throat, thirst, and weakness were then noticed, and diagnosed by his doctor as influenza. The thirst and weakness increased, and some polyuria developed; he became constipated, and on the day before admission was drowsy. On admission he was semi-comatose and "dyspnœic," with a pulse of 110 (no note as to volume). The treatment and progress for the first four days are shown in Table I.

TABLE I. (Case 1.)

Date in Feb., 1924.	Blood.		Urine.				Treatment.	
	Sugar %.	Urea %.	Vol. oz.	Sugar.	Acetone bodies (FeCl$_3$).	Albumin.	Fluids.	Insulin. units.
6th	0·64	—	10 +C‖	+ +	+ +	+	See below.	50
7th	0·147	0·063	20 +C	+ + +	+ +	Nil		60
8th	—	—	34	—	—	—		60
9th	0·09	—	94	—	—	—		45

‖ C = One catheter specimen, volume not measured.

Fluids.—6th, 7th: 15 oz. hrly. gluc. and bicarb. rectally and mouth. 8th: Solid food started.

He was discharged "sugar-free" on 25 units of insulin night and morning, and on a fairly liberal diet.

Four months later he was readmitted for investigation. With no alteration in his diet and without insulin he remained sugar-free, and his blood-sugar at 5.30 P.M. was 0·135 per cent. He was discharged on a diet without insulin.

Notes.—Urine: There appears to have been a distinct drop in the volume of urine passed at the onset of coma, since he had been passing large quantities just before. Notwithstanding the considerable quantity of fluid given diuresis did not occur for two days, and then coincided with a complete return to consciousness. Blood-urea: On the second day, when the patient had almost recovered, the blood-urea was still twice the normal value. Subsequent history: This case is remarkable in that so severe a case of diabetes, requiring 50 units of insulin daily to keep the urine sugar-free, should have recovered to such a degree as to permit the omission of insulin, at any rate for the time being.

CASE 2.—E. K., aged 18, female. Admitted under the care of Dr. H. French. History of diabetes for two and a half years, treated by diet. Fourteen days before admission the patient complained of a sore-throat and became constipated. An enema was followed by some improvement. Two days before admission patient collapsed and vomited. The next day there was no improvement, vomiting continued, and there was much thirst. On the day of admission she became dazed, and when admitted she was comatose with some delirium, the respirations were deep and quick, and the pulse rapid and feeble. Treatment and progress are shown in Table II.

TABLE II. (Case 2.)

Date in Sept., 1924.		Blood.		Urine.				Treatment.	
		Sugar %.	Urea %.	Vol. oz.	Sugar %.	Acetone bodies.	Albumin	Fluids.	Insulin units.

11th:	8 A.M.	0·50	0·198	4	F.tr.	Nil.	+		40

F. tr. = Faint trace.

Fluids.—7th: 25 oz. sodii bicarb., 50 oz. gluc., intrav. 8th: 20 oz. sodii bicarb. and gluc. 2-hrly. by nasal tube. 9th: 20 oz. gluc. intrav. 10th: 20 oz. fluid, 2-hrly., rectally.

Remarks.—7th: Comatose and vomiting. 8th: (8 A.M.) Conscious; (4 P.M.) still vomiting; (12 P.M.) comatose again. 9th: (8 A.M.) Sweating; (4 P.M.) air hunger, hot skin; (12 P.M.) vomited. 10th: No air hunger. 11th: Air hunger; commencing gangrene right big toe; (4 P.M.) died.

Post-mortem examination showed no naked-eye abnormalities in heart, lungs, kidneys, &c., but gangrene and perforation of the ileum had occurred, and there was some pus in the pelvis.

Notes.—Urine: A marked feature in this case was the oliguria. Although the blood-sugar was extremely high, only traces of sugar were passed in the last 73 hours. Albumin was constantly present. The absence of acetone bodies was probably due to the inability of the kidney to excrete them (vide Case 8). Blood-urea: The significance of so high a figure is doubtful, as the patient was moribund, in which condition a high blood-urea is sometimes found.[10] Vomiting: It is extremely difficult to assess the diagnostic importance of this persistent vomiting. It occurred in three other cases of coma (Cases 6, 10, and 11); but in view of the post-mortem findings it is impossible to rule out an intra-abdominal cause, although it is probable that the gangrene and perforation of the ileum was a terminal event comparable with the gangrene of the toe.

CASE 3.—L. B., aged 19, male. Admitted under the care of Dr. Beddard. History of diabetes for one and a half to two years. He had been having 5 units of insulin daily for the five months previous to his admission. On the day preceding admission the insulin was omitted and he had a tooth extracted. By the next day he was comatose, and when admitted there was definite air hunger. The treatment and progress are shown in Table III., with the exception of the fluid given, notes of which are available for the first 24 hours only. During this time 10 oz. saline, containing sodii bicarb. and glucose, were given every hour by nasal tube, and 20 oz. saline subcutaneously and 40 oz. saline rectally.

When discharged the patient was having 25 units three times a day, with a diet containing 2 oz. potatoes and 3 oz. bread. When seen six months later, apparently on the same régime, his blood-sugar was 0·28 per cent., and 120 units of insulin a day were required to render his urine sugar-free. When last seen in March, 1925, he was in excellent health, and his blood-sugar was 0·15 at 2 P.M. He was having only 50 units of insulin a day.

---

* The chief points in this paper were communicated to a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine.

TABLE III. (Case 3.)

Date in 1924.	Blood.		Urine.				Units of insulin.

(C) = Catheter specimen.

Remarks.—Oct. 25th: Coma. 26th: Drowsy. 27th: Hypoglycæmia. 28th: Drowsy. 29th: Earache and aural discharge.

Notes.—Urine: A certain degree of oliguria is to be noted, and diuresis did not start for five or six days, the patient having completely recovered from the coma. Albumin was present until diuresis started. Blood-urea: Even on the third day the blood-urea was over five times the normal value. With complete recovery the blood-urea returned to normal. Coma: In this case although some sugar was given, at the end of 48 hours signs of hypoglycæmia appeared (noisy delirium, sweating, full pulse). On omitting insulin, within 24 hours the patient became drowsy again, as if diabetic coma were impending. Insulin treatment was restarted, less being given than before, and in a few days the effects of the coma had quite cleared up.

CASE 4.—L. S., aged 15, female. Admitted under the care of Dr. Beddard. History of two months' weakness. Tubercle being suspected, the patient was sent to a sanatorium about a week before admission to Guy's. While there she "caught a cold" and became tired and drowsy. She was sent home, and the next day she was admitted almost comatose with air-hunger. (Table IV.)

TABLE IV. (Case 4.)

Date in 1924.	Blood.		Urine.				Treatment.

Sept. 18th: 5.15 P.M. ..	0·12	—	?	Nil	Nil	Nil		40

N.N. = Nearly normal.

Fluids.—August 27th: 20 oz. gluc. and $NaHCO_3$; stomach-tube. 28th: Fluids ad lib.; no record of quantity.

Remarks.—August 27th: Coma. 28th: Recovered consciousness.

Notes.—Urine: Slight oliguria is to be noticed. Albumin appears to clear up about the same time that the volume of urine increases. Coma: Although no symptoms of hypoglycæmia were noted, it is evident from the blood-sugar that within a few hours of coming out of diabetic coma the patient is close on an insulin reaction.

CASE 5.—R. E., aged 17, male. Admitted under the care of Dr. Poulton. History of one week's illness, starting with a sore-throat. On admission he was semi-comatose. He had well-marked air-hunger, but his pulse was good. (Table V.)

He was discharged Nov. 13th, 1924, in good health, having 50 units of insulin and an adequate diet. Six months later the urine was sugar-free, and the blood-sugar at 1 P.M. was 0·13 per cent., while he was taking 8 units of insulin at night.

TABLE V. (Case 5.)

Date in Sept., 1924.	Blood.		Urine.				Treatment.

2–5 P.M.	0·12	—	—	—	—	—		
26th	—	—	88	+	Tr.	—		35

Fluids.—24th: 100 oz. Saline by mouth for 5 hours. Vomited and fluids discontinued for 5 hours. 25th: 200 oz. Saline $NaHCO_3$ by nasal tube.

Remarks.—24th: Coma. 25th: Regained consciousness.

Notes.—Urine: No oliguria was present in this case. This probably is associated with the unusually good pulse. Blood-urea: Was twice the normal value, notwithstanding the quantity of urine secreted.

The subsequent history of this case is of interest. He was admitted in May, 1925, passing sugar and a fresh régime was arranged, but he did not keep to his diet. At the end of August he went to bed feeling unwell (no other details obtained), but got up on Sept. 4th, went out, and apparently ate unrestrainedly. He took no insulin that night, and the next day he was sleepy, and insulin was again omitted. Early on the 6th he was readmitted very drowsy, but able to answer questions. Energetic treatment was at once started, but in spite of 100 units of insulin and much fluid he died in a few hours. His blood-sugar shortly before death was 0·49 per cent. He passed no urine after an initial catheter specimen. Post mortem his bladder was empty and the kidneys were large with some fatty changes. No other abnormalities were found.

CASE 6.—M. J., aged 17, female. Admitted under the care of Dr. Beddard. Two or three months' history of lassitude, thirst, loss of weight and poor appetite. On the evening of the day preceding admission she suddenly vomited and became drowsy. The vomiting continued, and the drowsiness increased; on the next day she was admitted completely comatose, with deep but not rapid breathing. (Table VI.)

TABLE VI. (Case 6.)

June 20th	0·09	0·013	—	—	—	—	—	60

Fluids.—May 27th: 60 oz. per rectum, "several pints" by mouth of saline, with glucose and $NaHCO_3$.

Remarks.—May 27th: Coma. 28th: Recovered consciousness. 31st: Aural discharge noted June 6th.

The patient was discharged some weeks later quite fit on a diet and 60 units of insulin a day.

Notes.—Urine: The absence of reliable figures prevents any remark on the volume. Albumin was present and disappeared on the complete recovery of the patient.

CASE 7.—I. M., aged 16, female. Admitted under the care of Dr. Poulton. Admitted in coma. She did not regain consciousness, and died the next day. No record as to history was obtained. (Table VII.)

TABLE VII. (Case 7.)

Date in Sept., 1924.	Blood.		Urine.				Units insulin.
	Sugar %.	Urea. %.	Vol. oz.	Sugar.	Acetone bodies ($FeCl_3$).	Albumin.	
7th ..	0·5+	0·135	?	+	(+)	+	40
8th ..	—	—	?	++	Nil	—	120

Remarks.—7th: Coma. 8th: Death.

Note.—The main points of interest in this case are the high blood-urea a day before death, and the very small amount of acetone bodies in the urine.

CASE 8.—E. P., aged 29, female. This patient is Case 6 in a previous publication (THE LANCET, p. 777, 1923). Her history dates back two years. She had been having insulin treatment at home for some months. She was there seen by one of us in consultation with Dr. Wilson. She was then tired and had a bad cold. No sugar was found in the urine, and insulin had been omitted. Insulin was given again. The next day she became drowsy and had pains in her back. Sugar and acetone bodies appeared in the urine. On the following morning there was more drowsiness and some exophthalmos, and in the afternoon the patient became comatose and the breathing deep. Insulin continued to be given, but no urine could be obtained. A lumbar puncture was performed. Some improvement resulted which continued for some days, although there was some vomiting. A specimen of urine was obtained by catheter at the time of the lumbar puncture. The patient died a few weeks later, but no details were obtainable. (Table VIII.)

TABLE VIII. (Case 8.)

—	Vol.	Sugar.	Acetone bodies.	Urea.	—
Blood ..	—	0·46	—	—	—
Urine ..	?	Nil	Nil	—	—
C.S.F. ..	14 c.cm. removed.	—	$FeCl_3$ + Legal + +	0·16 %	Cells 0. Protein 0·05 %

Notes.—The striking points in this case were: (1) The high blood-sugar with no sugar in the urine. (2) Acetone bodies present in the C.S.F., but absent in the urine. (3) The high urea content of the C.S.F. (4) The pronounced oliguria.

CASE 9.—O. B., aged 19, female. Seen by one of us in consultation with Dr. H. P. Warner, of Woodford Green. Two years' history of malaise. Thirst was noticed two weeks previously, and four days previously the urine was found to contain 7 per cent. sugar, when the diagnosis of diabetes was made. She became drowsy early in the day, and by the evening was in coma. No urine was passed during the day. Sixteen months later she required 42 units of insulin a day, and with this the blood-sugar was 0·17 per cent., and the urine nearly always sugar-free. (Table IX.)

TABLE IX. (Case 9.)

Date in Dec., 1923.	Blood.		Urine.				Treatment.	
	Sugar %.	Urea %.	Vol. oz.	Sugar	Acetone bodies.	Albumin.	Insulin.	Fluids.
14th	0·45	0·077	13 (cath.)	1 %	+ + +	+	50 units at once, 30 units 4-hrly.	See below.
15th	—	—	60	—	—	—		
16th	—	—	70	—	—	—	—	
17th	—	—	65	—	—	Nil	—	

Fluids.—14th and 15th, 40 oz. saline with glucose and $NaHCO_3$, by nasal tube every hour.

Notes.—This case shows the preliminary oliguria with albumin in the urine and a raised blood-urea. With the onset of diuresis the albumin disappeared.

CASE 10.—K. A., aged 20, male. History of diabetes for two years. He was living at home on a protein-fat-vegetable diet, and was having 45 units of insulin a day. On this he was keeping very well, and was able to do all the work he wished to. On Wednesday, July 16th, 1924, he caught a chill and went to bed. He was still in bed on Friday, and he started to vomit. Insulin had been given as usual up to Friday morning, when it was omitted. On Friday night 30 units of insulin were given with some sugar, as he was drowsy. He died early Saturday morning. No other details were obtainable.

CASE 11.—J. W., aged 11, female. This child had had diabetes for about two years, and had done very well with insulin treatment at home. Her dose was 8 units in the morning and 16 units at night. On Thursday, July 31st, 1924, she had a temperature and was put to bed. Insulin was given as usual. On Friday she had a fluid diet and only 4 units of insulin. On Saturday the temperature became normal, but vomiting commenced and there was some air-hunger. The diet was still restricted to fluids and insulin was omitted. On Sunday some morphia was administered and the vomiting, which had been very persistent, ceased. At 8 A.M. she received 16 units of insulin, as there was much glycosuria. At midday 20 units of insulin and a rectal injection of glucose and sodii bicarb. were given, followed by 16 units of insulin and rectal glucose four-hourly, bringing the total amount of insulin to 68 units. On Monday she received 32 units of insulin, but became semi-comatose and her pulse began to fail. As she appeared to be in pain morphia was again administered. Death occurred at midday.

Notes (Cases 10 and 11).—There is a certain similarity in these two cases. In both a febrile attack was followed by vomiting, coma and death, and in both the dose of insulin was diminished. In both cases, when ultimately the seriousness of the condition became evident, the correct treatment of insulin and sugar was started, but in neither case were the quantities of insulin and fluids given as great as were found necessary in the cases treated in hospital.

Discussion.

Length of History.—Cases 1, 4, and 5 show the remarkable acuteness of onset of which diabetes is capable, the illness apparently dating back only seven days in Case 5.

Age.—In our series 9 of the 11 were between 11 and 20 years old, the remaining two being 25 and 28. This, however, is hardly a fair representation of the age-incidence of coma as the literature abounds with cases between 30 and 60, usually terminating a fairly long history of diabetes mellitus.

Onset.—The apparent cause of onset in many of our cases was a febrile disturbance such as a sore-throat or a cold. In three cases (3, 10, and 11) who were receiving insulin, coma started within a day of omitting insulin, either on account of a febrile disturbance or operative interference. Vomiting also appears often to precede coma (Cases 2, 6, 10, 11), this symptom occurring fairly frequently in histories of many reported cases.

Renal Element.—The renal element in diabetic coma appears to have escaped attention during the last few decades. Recently several investigators have recorded cases in which some renal failure is evident. Warburg [1] in particular has reported four cases and reviewed the literature with reference to diabetic coma as far back as 1844, when Bouchardat recorded two cases of diabetes who died in coma. In both of these before the onset of coma the urine contained much sugar, but during the 24 hours preceding death the urine contained no sugar. Between that date and 1897 there are many cases recorded in which diabetics died in coma with either anuria, or oliguria, or albuminuria with or without casts. The first record of definite urea retention in a case of diabetic coma was in 1868, when Colin notes that the blood from the veins at post-mortem contained a definite excess of urea. More recently Rosenblom,[2] Joslin,[3] Höst,[4] Rahlff,[5] Paddock [6] have recorded cases of coma in which the urine, while containing sugar, failed to show any ketone bodies; albuminuria was present in almost all cases. Mördre [7] has recorded a case in which the urine showed the presence of sugar and albumin with absence of ketone bodies, and in which the blood-urea was much raised, and Imrie and Skinner [10] record a similar case with anuria and a raised blood-urea.

These cases, except Warburg's and Imrie's and Skinner's, were treated before the days of insulin, and they all died, with the exception of Rahlff's case and two of Warburg's. The latter two cases showed some oliguria, albuminuria, absence of ketone bodies, and a raised blood-urea. The albuminuria disappeared and the blood-urea returned to normal with recovery. In Warburg's two fatal cases ketone bodies were absent from the urine. Brunton [11] has recorded two cases of diabetic coma successfully treated, in one of which there was a raised blood-urea which returned to normal. He also examined the blood-urea of several other diabetics not in coma and found figures within the normal range. No note as to the urine was made.

In a somewhat different category are the cases recorded by McCay and his co-workers.[12] He found that the Bengali leading a sedentary life and becoming obese was afflicted with a mild type of diabetes which often terminated in coma. He examined a number of cases and found a marked urea and non-protein nitrogen retention. The blood-sugar was raised. The urine showed albuminuria and casts and contained only small amounts of sugar, while the ketone bodies were present in traces only or were absent.

These cases were uniformly fatal, and McCay regards them as dying of uræmic coma following a prolonged deterioration of the kidney, but he had no opportunity of examining them before they were admitted in the early stages of coma, and apparently no microscopical examination of the kidneys was made. They may well have been, therefore, cases of diabetic coma with terminal renal failure.

An examination of the nine cases observed by us affords further evidence of the part played by the kidney in diabetic coma. In six cases oliguria was certainly present, and in eight cases there was albuminuria. The blood-urea was measured at the time of coma in seven cases, and in six of them it was abnormally high. Three of the cases (2, 7, and 8) observed by us terminated fatally in spite of insulin treatment, and in these the blood-urea ranged from 0·135 to 0·198 per cent. In only one case that recovered was such a high value found. In two of the fatal cases (2 and 8) the severe degree of renal failure was suggested by two further facts: (1) in spite of a very high blood-sugar, sugar was absent from the urine or present in traces only at some time during the coma; (2) the urine contained no acetone bodies.

In all the cases recorded up to date in which the urine showed no ketone bodies their presence in the body fluids has been assumed. In Case 8 this evidence was obtained by examination of the cerebro-spinal fluid. It has been shown also in a previous paper [12] that the kidney in coma does not concentrate ketone bodies as well as it does when coma is not present. (Table II. of the latter paper shows that in Cases 3 and 5 the concentration of ketone bodies in the urine was about ten times that of the blood, while in Case 4 in coma the concentration in the urine was only two or three times that of the blood.)

The cause of the renal failure is by no means clear. It is usually considered that the kidney, in common with other organs, is poisoned by the ketone bodies, and in particular by aceto-acetic acid. While this poisonous action undoubtedly exists it does not explain why a kidney which has for a long time successfully dealt with large quantities of ketone bodies suddenly fails and permits them to accumulate.

Other possibilities must therefore be considered. There are several.

1. The poisonous action exerted by the excess of sugar in the blood. The height of the blood-sugar in coma is indeed striking in some cases. Joslin [4] has recorded a blood-sugar as high as 1·37 per cent. There are records of cases in coma with blood-sugars below 0·4 per cent., and diabetics not in coma are fairly often seen with a higher blood-sugar than this. However a blood-sugar above 0·4 per cent. is undoubtedly very common in coma. In seven of our cases the blood-sugar was estimated at the time of coma. The lowest value was 0·36 per cent., and all the other values were above 0·4 per cent.

2. Other toxins may be formed (suggested by Paddock, Rosenblom, McCaskey). There is, however, very little evidence of them.

3. The ketone bodies may poison the heart muscle and the circulatory failure may cause renal failure with oliguria and further accumulation of poisons. (This cause for oliguria was pointed out by Frederick Taylor in 1880.) That circulatory failure is characteristic of diabetic coma is shown by the feeble pulse and diminished intra-ocular tension that occur so commonly. However, in Case 8 the pulse appeared to one of us perfectly normal, and yet the blood-urea was 0·66 per cent., so that circulatory failure will not explain this matter completely.

4. The preceding polyuria noted in many cases, or the vomiting in others, may completely deplete the water reservoirs of the patient, the kidney thus becoming unable to excrete the poisonous ketone bodies owing to lack of the necessary water. The almost constant marked dehydration of a coma patient adds support to this, and the recovery, if only temporary, which has frequently been noticed to follow the intravenous injection of large volumes of salines also points in the same direction. The diuretic effect of high blood-sugar [10] would also account for the close association between a high blood-sugar and coma.

5. The ketone bodies may be produced so very rapidly that the kidney is unable to cope with them. This is probably what occurs in the cases of coma occurring within the first few weeks of the disease.

The last three factors probably account together or separately for the majority of cases of coma, and also for the different types of case (cf. Dreschfeld [8] and Frerichs,[9] quoted by Warburg, and the report of the Insulin Committee.[11])

Prognosis.

All the cases of diabetic coma in this paper were young subjects. With efficient insulin treatment the most important immediate cause of death at the present day would appear to be renal failure, as indicated by prolonged oliguria, high blood-urea, and the excretion of mere traces of sugar or acetone bodies in the urine. Albuminuria is practically always present and so will not influence the prognosis. After recovery from coma there is no tendency to relapse into coma provided insulin treatment is continued. The ultimate severity of the case, as judged by the amount of insulin required, depends largely on the length of time the patient has had diabetes, if insulin has not been given previous to the coma, because the disease is naturally progressive in young subjects.

Our figures so far as they go support this view. The amount of recovery in Cases 1 and 5, where the history was short, is remarkable. Enocksson [14] has recorded an even more striking success in a child who, within three months of recovery from coma, showed a perfectly normal tolerance to carbohydrates. This was unfortunately broken down by carbohydrate overfeeding, but on a suitable diet returned almost to normal again.

Diagnosis.

In view of the above results it is obvious that some cases of diabetic coma closely resemble uræmic coma. Take, for example, Case 8, where the urine showed no sugar or ketone bodies and where there was also urea retention. Such a case seen for the first time without a history would undoubtedly be diagnosed as uræmia, and only the estimation of the blood-sugar would indicate the correct diagnosis, and even here care in the interpretation of the result is required, since in chronic nephritis the blood-sugar tends to be slightly high. Further points in favour of uræmia in young subjects would be a blood pressure over 150 mm. and the presence of retinal changes, since diabetic retinitis (even if it exists, which is doubtful, and is not merely secondary to a coincident hyperplastic sclerosis, senile calcification or Monckeberg's sclerosis) is never, in our experience, met with in young subjects. As we are now able to combat diabetic coma by means of insulin with a good chance of success it is important that cases should not be missed, and in all cases of suspected uræmic coma where the history is doubtful blood-sugar estimations should be made.

Prevention of Diabetic Coma.

L. Blum has pointed out that patients who have been treated with insulin may pass rapidly into coma if insulin is suddenly stopped. The explanation is that owing to the insulin such patients have put on much weight in the form of fat. But fat is the chief source of ketone bodies, so that the latter are immediately formed in large quantity if the carbohydrate metabolism is suddenly interfered with by omitting insulin. As a contrast the case may be cited of a man, aged 54, seen by one of us in consultation with Dr. Bent before the insulin days. As the result of a four years' history of diabetes, he had been reduced to a mere skeleton. The urine gave a very faint Rothera reaction four days before his death, which was not from coma, but rather from inanition. The ketosis was presumably absent because the body fat had practically disappeared. The elderly patient with diabetes is not in danger of diabetic coma, and such people are able to take a course of insulin treatment and obtain the full benefit from it, and they may then omit insulin when they like.

The risk that acute infection may precipitate coma has long been known. Out of ten of our cases where the notes are complete, a history of acute infection immediately preceding the coma was obtained in no less than seven, and this took the form of "sore-throat," "cold," "chill," or "temperature." It is thus obviously of great importance to protect patients with diabetes from acute catarrhal infections of the respiratory mucous membranes by means of face masks made of butter muslin, by Glegg's paraffin and vaseline treatment,[15] by prophylactic vaccination, &c. If infection occurs the insulin must be continued, and if glycosuria and ketosis supervene the dose should be increased and extra carbohydrates should be given for the time being. The bowels should be kept open and plenty of fluid should be taken by the mouth.

The Treatment of Diabetic Coma.

Our general views on the treatment of diabetic coma have already been given by one of us,[16] so that a brief summary is all that is necessary at present. Massive doses of insulin (20–40 units) are given every four hours, and at the beginning an intravenous injection of 10–20 units may be given if the case is urgent. The frequency of urea retention makes it important to give large volumes of fluid, so as to keep up the flow of urine. It is hardly ever necessary to give an intravenous injection of fluid because the latter can be absorbed rapidly and in larger quantity from the alimentary canal. If the patient cannot take one pint of fluid every hour by mouth, it should be passed directly into the stomach or duodenum through a nasal or Einhorn's tube, with the patient lying on the right side. The fluid should be isotonic, sugar, sodium bicarbonate, and a little salt being dissolved in tap water. A more accurate prescription is as follows: Dextrose 3 per cent., sodii bicarb. 0·5 per cent., potassium chloride 0·05 per cent., calcium chloride 0·03 per cent.

A look out must be kept on the bases of the lungs to see that œdema does not develop. The rapidity with which energetic treatment with insulin may cause diabetic coma to pass into hypoglycæmic coma without the patient recovering consciousness in between has been pointed out by Graham [17] and by one of us,[16] and is illustrated by Case 3 of the present paper. In the absence of blood-sugar examinations at frequent intervals, the plan of testing the urine at two-hourly intervals has been advocated, so that the administration of insulin may be temporarily stopped as soon as the urine is sugar free and only continued again when sugar returns. Such a plan would have failed in two of our cases, because the urine did not contain sugar even though the blood-sugar was high. It would be better to take account also of the ketone bodies of the urine by means of Rothera's and the $FeCl_3$ tests, because in hypoglycæmia both sugar and ketone bodies disappear from the urine; but even this plan would not have answered in our two fatal cases. Undoubtedly the safest plan is to continue giving sugar by mouth at frequent intervals until an abundant flow of urine is definitely established, and when this is the case sugar and ketone bodies will no longer be retained by the kidneys, and the urine will give a true index of the amount of hyperglycæmia and ketones in the body. The fluid intake may then be diminished and the sugar omitted, and the insulin should then be continued until the urine is sugar-free and free from ketones when tested at two-hourly intervals. Our subsequent treatment has been fully described elsewhere.[16]

Finally, we should like to thank the physicians at Guy's Hospital for facilities for examining their cases, and in particular we should like to thank Dr. J. H. Ryffel for permission to quote some of the analyses carried out by him. Part of the expenses of this investigation were defrayed out of a grant to one of us from the Medical Research Council.

Summary.

1. Eleven cases of diabetic coma have been reported and certain cases reviewed from current literature. 2. A definite renal element as shown by oliguria, albuminuria, and urea retention and failure to excrete ketone bodies, and occasionally sugar, is present. 3. In some cases this renal failure is so decided as to cause a marked resemblance to uræmic coma. 4. The cause of the renal failure has been discussed. 5. The treatment is carried out by means of large injections of insulin, and by the administration of much fluid, containing dextrose, by the mouth.

Note.—Since sending in this paper for publication, an interesting article by Dr. A. Clarke Begg has reopened the question (THE LANCET, July 11th, 1925, p. 69). In view of the present observations we would urge with Dr. C. G. Imrie (ibid., 251) that it is better not to divide up cases of diabetic coma into two distinct groups, since renal insufficiency in varying degree was present in practically all our nine consecutive cases. Further, we suggest that his cases, like our Case 8, were really acetonæmic, but that the kidneys fail to excrete the ketone bodies, and that the most rapid means of introducing fluid, which is urgently required by the body, is through the alimentary canal by nasal tube.

THE TRANSMISSIBLE BACTERIAL LYSIN AND ITS ACTION ON DEAD BACTERIA.

BY FREDERICK W. TWORT.

(From the Laboratories of the Brown Institution, University of London.)

SINCE my first publication in THE LANCET in 1915 on the transmissible lysin to be found in association with micrococci and with bacteria of the dysentery-typhoid-coli group, a large number of papers have been published by different workers, and the literature on the subject at the present time is extensive. It is, however, not my purpose in this paper to do more than record a few additional experiments which I have carried out during the past six months.

No agreement has yet been reached as to the nature of the lytic agent, but, in the controversy that has centred round this important point, the absence of any definite action by this substance on dead bacteria has been used both in support of and against the view that it is an ultra-microscopic virus. It is therefore of interest to record that from my recent experiments it appears certain that dead bacteria, under special circumstances, are attacked and lysed.

A new strain of the lysable white micrococcus and fresh active lysin were obtained from vaccinia. The micrococcus was isolated free from lysin, and grown on agar slopes for 24 hours; from these a moderately turbid emulsion was made with normal saline. The emulsion was heated in a water-bath at 60° C. for one hour, then mixed with an equal quantity of ordinary sterile peptone-beef broth, and 2 c.cm. of the mixture pipetted into each of four sterile test-tubes.

Tube 1 received no addition.

Tube 2 was inoculated with a loopful of pure living micrococcus.

Tube 3 was inoculated with 2 drops of filtered lysin.

Tube 4 was inoculated with 2 drops of filtered lysin and a loopful of the living micrococcus.

The Standard Experiment.

This experiment throughout the paper will be referred to as the standard experiment. The four tubes were incubated at 37° C. After 24 hours tubes 1 and 3 showed no visible change. Tube 2 showed an increase of turbidity, while tube 4 showed a marked clearing of the emulsion. The experiment has been repeated a number of times with a similar result, although the time taken for tube 4 to clear may vary from one to three days according to the activity of the lysin used. It is worthy of note that a good result is also obtained if the coccus emulsion is prepared from cultures which are a week or more old, and with an emulsion heated at 75°–100° C., or when it is autoclaved at 120° C. for five minutes. Tube 4 in the experiment never seems to clear completely, but the opacity left is certainly in part due to the survival of some of the living bacteria, as can be proved by plating out the emulsion. The result is best shown when the dead coccus emulsion is not too thick, otherwise there will be insufficient fresh lytic agent produced to act on the maximum proportion of cocci in the emulsion. It is not essential to add broth to the saline emulsion of cocci, but without this the action is usually slower.

The experiments show clearly that there is *lysis of dead bacteria* when the lytic agent is being *freshly* produced in the presence of living bacteria of the same variety. In other words, that the lysin will act on both dead and living bacteria, but is only produced—*or possibly activated*—in the presence of the living. If the lytic agent is so activated or complemented by some thermolabile substance present in the living bacteria, it is a little surprising that the lysin, in the absence of living bacteria, does not act on the dead emulsion, seeing that the lytic agent in the experiments is mixed with broken-down products of living bacteria. It may, however, be that such a complementary agent, if present, is used up as fast as it is formed, and is therefore not free in sufficient quantity to produce any visible action. We know, from hæmolytic and many similar experiments, that such reactions are rarely simple in nature, and it seems probable from the experiments described here that the lytic agent consists of at least two portions, whatever the nature of these portions may be.

It may be recalled that d'Herelle in his work on the transmissible lysin—"bacteriophage"—claims to have separated a non-transmissible lysin from a transmissible virus, and if future experiments should prove the ultra-microscopic virus theory to be the correct one, then the experiments I have described might indicate that whereas the virus will grow only on the living bacteria, the lysin secreted by the virus will act on both the living and the dead, although the living may be first killed by the virus.

The Question of a Complementary Agent.

Some experiments were now carried out to test for the presence of a complementary agent that might be contained in living bacteria. The lysable micrococcus—free from the lytic agent—used in the standard experiment was grown in ordinary peptone-beef broth for three days at 37° C., and the culture then passed through a Doulton brown filter. The sterile filtrate was mixed with an equal quantity of fresh sterile broth, care being taken to avoid contaminations. This mixture was added to the emulsion of dead micrococci in place of ordinary broth which was used in the standard experiment, and the whole distributed into four test-tubes. Tube 1 was heated to 65° C. for an hour, and the tubes then inoculated as in the standard experiment—that is, tube 1 received no addition, tube 2 was inoculated with a loopful of living micrococcus, tube 3 received two drops of lysin, while tube 4 was inoculated with a loopful of coccus in addition to two drops of lysin. The experiment was repeated with slight variations. In some cases a much larger quantity of the filtered lysin was added, and in other instances, where an older broth culture was used, the filtrate of this was mixed with twice or three times its volume of fresh sterile broth before being mixed in equal quantity with the dead bacterial emulsion. In none of the experiments, however, was there any evidence of lysis in tube 3, the emulsion remaining as opalescent as in tube 1. Tube 4 in these experiments showed the same lysis of the emulsion as was observed in the standard experiment. It is clear from the absence of any lysis in tube 3, that the living micrococcus cannot be replaced by filtrates of the coccus growth. The experiments described, however, are not sufficient to prove that no complementary agent exists in the bacterial protoplasm, and it is intended to carry out further experiments to probe this question thoroughly.

In some other experiments a small quantity of fresh serum from a guinea-pig was added to the tubes which in other respects were set up in the manner of the standard experiment. This, however, did not activate the lysin in the absence of the living coccus. Tube 3 remained as opalescent as tube 1, while lysis took place only in tube 4.

Comparative Tests.

In carrying out these experiments comparative tests were usually made with emulsions of other bacteria which were killed at 60° C. and used in place of the lysable micrococcus. The bacteria included a slow-growing micrococcus also obtained from vaccinia, and giving a dense white heaped-up growth, the Shiga type of dysentery bacillus and *Bacillus phlei*. In each case four tubes were put up, and these were inoculated as in the standard experiment, and incubated as before. All the results were negative, there being no lysis of any of the emulsions, indicating that the lysin, in the presence of living cocci, is as specific in its action on dead bacteria as it is when they are living. This result is of particular interest in connexion with experiments that have been carried out by many workers who *appear* to have acclimatised a lysin for one bacterium to act upon another. If, however, the lytic agent is not of the nature of a virus, it would appear more likely in the acclimatisation experiments that a new variety of lysin, or possibly the specific portion of a double body, has been produced from the second bacterium, or the lytic agent may have always been present with the second bacterium, and been stimulated to start its cycle of activity. In any case it seems clear that the lysins associated with different bacteria cannot be identical, for while resistance of the bacterium may play a part in preventing any action in the case of the living bacterium, this cannot be so with emulsions heated as high as 120° C.

The Temperature at which Lysin is Destroyed.

In my original paper on the transmissible lysin, associated with the micrococcus to be obtained from vaccinia, it was stated that the lysin appeared to be destroyed at 60° C. Many workers have since given a higher temperature, while some have stated that there is not complete destruction at 65° C. In view of the different results obtained, I have recently carried out a large number of experiments to re-test this point. My original tests were carried out in the following manner: Agar streaks of the micrococcus showing well-marked lysis were taken and the growth washed off with 0.85 per cent. NaCl. This was made up to 200 c.cm. with a further quantity of saline and passed through a Doulton white filter. The filtrate was then run into long capillary tubes, and these placed, completely immersed, in a water-bath regulated at the temperature to be tested. On repeating the experiment in this way I have found that the lysin is usually destroyed at 60° C. in one hour. If, on the other hand, the filtrate is placed in a sterile test-tube plugged with cotton-wool, there is nearly always a small amount of lysin left undestroyed. Such a method, however, cannot be relied upon to give accurate results. It has been found also that if the lysed cocci are mixed with the condensation water of the agar tube, and the concentrated lysin drawn into capillary tubes, and heated to 60° C. for an hour, the lysin is probably never destroyed completely. Various other circumstances, which for lack of space cannot be considered in this paper, appear to affect to a small extent the temperature at which the lysin is completely destroyed. It is also possible that the lysins associated with different bacteria are not all destroyed at exactly the same temperature.

There is one additional point of some interest that has been observed when carrying out these experiments. When a diluted lysin, which has been almost completely destroyed, is pipetted down a number of agar slopes which are then streaked down with the coccus and incubated at 37° C., the growth obtained is often a continuous white streak entirely free from clear areas. When subcultures are made from the primary growths on to fresh tubes of agar, these may also give a good white growth; but in the third or fourth subcultures, and sometimes in the second, a few clear areas may appear, and from these the active lysin can again be obtained. Moreover, the clear areas appear much more frequently in the third and fourth subcultures than is the case with similar areas arising "spontaneously" in a pure stock culture of the micrococcus. This seems to show that a growth of micrococcus, apparently free from lysin, may contain the lytic agent, although its action be masked or held in suspense. Most workers have considered this as one of the possible explanations of the lysed areas which occasionally appear to arise spontaneously in stock cultures supposed to be free from the lytic agent. It may be noted that d'Herelle has always put forward this suggestion when the spontaneous appearance of the lysin has been used as an argument against the virus theory. The experiments certainly indicate that it may in some instances be the correct explanation, although it is not necessarily the correct one in all cases.

Conclusion.

In my past papers I have discussed in considerable detail the possible nature of the ultra-microscopic viruses, and the possible relation of the transmissible lysin to these viruses. It will therefore be sufficient for me to observe in concluding this paper that there appears to be no definite proof that the transmissible lysin is a virus, although there are many arguments that may be used in support of this view. On the other hand, there are also many that may be used against it. It is probable that the question will remain unsettled until we know for certain the nature of these viruses. The experiments described in this paper appear to offer scope for further investigations along similar lines, and these in the future may throw some additional light on the problem.

HOSPITAL AIDS.—During the past year nearly £3000 was distributed to London hospitals and other philanthropic institutions by the Lion Hospital Aid Society. This little known organisation was formed in 1898 by the employees of Messrs. Lion, Lion, and Son, an East End firm of boot manufacturers. Its income in the first year was £70; it now exceeds £6000. The money is raised by collecting boxes, entertainments, and social gatherings.—The object of the Samaritan Fund of St. Bartholomew's Hospital, which has just reported upon its last year's work, is to assist patients after their discharge. The fund, which was formed in 1833, through the benevolence of Mr. Alexander Bennett, has aided 74,000 patients at a cost of £56,000, of which a little more than £1000 was spent last year. The help takes the form of money grants, railway fares, instruments, appliances, and convalescent treatment.

CANCER AND ACQUIRED RESISTANCE TO TUBERCLE.

BY THOMAS CHERRY, M.D., M.S.,

MELBOURNE.

A SUGGESTIVE feature in recent reports on public health from many parts of the world is the steady decline in the number of deaths from tubercle and the equally steady advance of cancer. In the first English records, more than 80 years ago, this reciprocal movement was already apparent, but at that time cancer was quite unimportant as compared with phthisis. By 1855 the phthisis-rate had fallen to 2000 per million, and the cancer-rate had advanced to 320. The two rates are now about equal in England and Wales. The changes which have taken place in the past 30 years and the percentage reduction and increase in the respective rates in each five-year period are as shown in Table I.[1]

TABLE I.—*Mortality Rates Per Million Living.*

Periods.	Phthisis.	Percentage reduction.	Cancer.	Percentage increase.
1871–5	2217	—	445	—
1876–80	2038	8·2	494	11·0
1881–6	1830	10·1	548	11·0
1886–90	1635	10·6	632	15·3
1891–5	1461	10·6	712	12·6
1896–1900	1323	9·4	800	12·3
1901–5	1218	8·0	867	8·4
1906–10	1106	8·4	939	8·3

The fact that the one disease appears to a large extent to be taking the place of the other may be a chance coincidence, and these figures cannot be applied to the problem without further analysis. Not only do the two diseases affect different periods of life, but in England the history of the rise of cancer and the decline of phthisis is different in the two sexes. While it is possible that occupation may have as great influence in the one case as in the other, this is at the present time little more than a surmise.

Perhaps the most important material bearing upon this question is the Supplementary Reports of the Registrar-General for the years 1891, 1901, and 1911. These contain an analysis of the deaths of all males over the age of 15 which were registered in the three consecutive years of each census period. Each report contains about half a million deaths classified by occupation, age, and causes of death. Table V. (Report, 1911, p. xxii.) gives the "Comparative Mortality Figures," or, in other words, the relative expectation of life, for most occupations. After deducting deaths by accident I selected occupations with approximately 200,000 deaths, half those with the best and half with the worst expectation of life. These may be arranged as under:—

	"Best" lives.	"Worst" lives.
Total deaths over 15 years ..	98,413	.. 100,011
Total deaths from cancer ..	9,745 (9·90 %) ..	9,306 (9·35 %)
Cancer under 65 years	5,011	.. 5,897
Deaths at 65 and over	52,366	.. 35,323
Cancer at 65 and over	4,734 (9·23 %) ..	3,409 (9·80 %)

When the cancer-rate is expressed as a percentage on the total number of deaths in each case it falls somewhat more heavily on the "best" lives. But cancer attains its greatest frequency about the age of 65, and a much larger proportion of the "best" lives reaches that age. If we express the rate for the age-period 65 as the percentage on all the deaths after 65 the rate is lower for the "worst" lives. Throughout this investigation the cancer-rate is calculated for any given age-period as a percentage on all the deaths from the beginning of that age-period to the end of life. In this way results are obtained as shown in Table II.

The large number of deaths from cancer in men following occupations corresponding to those represented by these "best" lives has probably created an

---

[1] Table VI., Statistical Review, 1921, p. 35.

TABLE II.—*Age-Incidence of Cancer on 200,000 Deaths (1911).*

Age-periods	25–	35–	45–	55–	65– to end.
"Best" lives ..	0·18	0·60	1·8	3·9	9·0
"Worst" lives ..	0·21	0·81	2·7	5·2	9·8

impression that cancer selects those in easy circumstances and passes by the poorer and the working-classes. But Table II., comprising nearly half the deaths of men in England during three years, proves that this is not the case. Cancer selects the survivors of the occupations which have involved a hard struggle for existence. The worst lives are more heavily hit at every age-period.

In order to test whether these results applied generally, I turned to Social Class 1 of this report (p. 3). This is described as "Upper and Middle Classes," and comprises, after deducting accidents, 45,557 deaths over the age of 25. Of these 45·8 per cent. were over the age of 65. Corresponding figures from the coal-miners are 20,002 deaths, of which 38·8 per cent. were over the age of 65. The expectation of life was therefore much better in Social Class 1, but on analysing the two groups of deaths (Table III.) the results are quite the opposite from those of Table I.

TABLE III.—*Cancer-Incidence by Age: Coal-Miners and Social Class 1 (1911).*

Age-periods	25–	35–	45–	55–	65– to end.
Coal-miners	0·26	0·82	2·8	4·4	6·6
Social Class 1.. ..	0·23	0·75	2·6	5·0	11·1

Thus in the last two age-periods, which are all-important in regard to cancer, the coal-miners were much better off than the upper and middle classes, whereas from Table I. we should have expected the opposite to be the case. Amongst the differences in the causes of death in these two classes of men is the fact that Social Class 1 has about 15 per cent. more deaths from phthisis than the miners at all ages, and that when the two age-periods 25–35 and 35–45 are taken as the basis of comparison this excess amounts to more than 25 per cent. I found that the percentage of phthisis on these two age-periods formed the best available index for the incidence of this disease at all age-periods, and on this basis 58,000 deaths were compiled from occupations in which the index was less than 3·10 and more than 8·50 respectively. Deaths by accident, all deaths under 25, and occupations in which the total deaths were less than 1000 were omitted from the lists (Table IV.).

TABLE IV.—*Age-Incidence of Cancer in Relation to Phthisis (1911).*

Age-periods	25–	35–	45–	55–	65– to end.
58,806 lowest phthisis	0·11	0·42	1·38	2·47	9·23
56,716 highest phthisis	0·30	1·00	2·25	5·60	9·80

It will be seen that in all the age-periods except the last the incidence in the low phthisis group is only about half of that in the high phthisis group. But in contrast to this striking co-relation of the two diseases we find that amongst the occupations included in both lists there were some, such as solicitors and barristers, which had a low phthisis and high cancer-rate, and conversely tool-makers and others which had high phthisis-rates associated with low cancer. On attempting to chart the occupations on the basis of cancer and phthisis for 1891 the results were not satisfactory.

It then struck me that we were comparing unlike things, that resistance to tubercle is probably established or lost fairly early in adult life, and therefore the proper method was to compare the incidence of cancer with the incidence of tubercle in the same occupation 25 or 30 years earlier. Unfortunately the details in the earlier census reports do not include the ages as well as the causes of death, and that for 1891 is the earliest available material.

From the report for 1891 I arranged according to their phthisis index the occupation that could be traced forward to 1911. This index was taken from the two age-periods 25–35 and 35–45. The cancer index is the sum of the four cancer percentages from 25–35 to 55–65. As before, occupations with less than 1000 deaths, deaths under 25, and accidents were omitted. The number of deaths available for analysis is about 320,000. The drift of the two diseases may be seen from the following groups of occupations (Table V.).

TABLE V.—*Groups of Occupations.*

Group.	Number of deaths.	Phthisis, 1891.	Index, 1911.	Cancer, 1891.	Index, 1911.
A	45,712	3·87	2·37	3·60	5·01
B	52,835	6·47	4·50	4·83	7·17
C	66,076	9·83	7·01	4·51	8·12
D	74,736	12·08	7·93	6·18	9·92
E	26,018	10·20	12·13	6·76	12·05
Total ..	265,977				

These groups comprise the following occupations:—

Group A.—1. Farmers. 2. Clergy. 3. Farm workmen. 4. Wheelwrights. 5. Coal merchants and retailers. 6. Sawyers.

Group B.—7. Brickmakers. 8. Gardeners. 9. Coal-miners. 10. Railway platelayers. 11. Fishermen. 12. Blacksmiths. 13. Greengrocers. 14. Inn-keepers. 15. Bargemen.

Group C.—16. Labourers (other than farm labourers).

Group D.—17. Railway officers and clerks. 18. Railway drivers and stokers. 19. Railway porters, guards, and signalmen. 20. Coach and bus drivers and grooms. 21. Draymen and carters. 22. Watchmen and messengers. 23. Engineers and boilermakers. 24. Iron manufacturers. 25. Painters and plumbers. 26. Printers. 27. Dyers. 28. Butchers. 29. Gas workers.

Group E.—30. Hotel employees. 31. Musicians and theatre employees. 32. Commercial travellers. 33. Commercial clerks. 34. Wharf labourers. 35. Coal-heavers. 36. Brass workers. 37. Paperhangers. 38. Brewers.

The incidence of cancer by age-periods in these groups is set out in Table VI. For convenience of comparison the results for 1911 are printed in italic type.

TABLE VI.—*Age-Incidence of Cancer, 1891 and 1911.*

Age-periods ..		25–	35–	45–	55–	65 to end.

Relationship of Decline and Increase Between Cancer and Phthisis.

From this analysis of more than 82 per cent. of the deaths available for this investigation the following results appear:—

1. When the groups are arranged on the basis of the phthisis percentage in 1891 the incidence of cancer in 1911 formed nearly a complete sequence for every age-period.

2. With few exceptions the occupations with both high phthisis and high cancer in 1891 increased at a much faster rate between these dates than those with the lowest phthisis and cancer-rates in 1891.

3. The incidence of cancer at all age-periods in 1911 was always light or heavy in accordance with the phthisis incidence on the same group.

4. During these 20 years there was no instance of an occupation which showed reduction in phthisis without showing increase in cancer.

This series of co-relations may be due to chance, for as the one disease is declining and the other increasing it is possible, though not very probable, that every occupation should be normal in both respects. If there is a causal relationship the cause must come out of phthisis and act upon cancer, for the one occurs early and the other late in life. The probability of cause and effect grows with each successive step, as we establish the following propositions:—

(*a*) A similar relationship of decline and increase cannot be demonstrated between cancer and any other disease or group of diseases.

(*b*) The co-relation of phthisis and cancer is found not only in the groups but in each of the 38 occupations which constitute the groups. Most of the occupations with less than 1000 deaths also fall in line. The few exceptions to this rule will be noticed subsequently.

(*c*) There is a recognisable element of proportion in the co-relation.

In a broad way we can say "a large increase in cancer means a large reduction in phthisis; little phthisis in 1891 and little cancer in 1911." I have not yet been able to define this element of proportion, but the following examples are sufficient to arrest attention. The course of the two diseases can be compared in a number of allied occupations. In such a group many variable factors are greatly simplified, such as the type of man, the question of inherited tendencies, the conditions of life and food-supply, and of wages. Such factors are more involved when we compare coal-miners with another social class than when we compare miners in Lancashire with those in Yorkshire (Table VII.).

TABLE VII.—*Phthisis and Cancer in Allied Occupations.*

		Phthisis index, 1891.	Cancer index, 1911.
Textile manufactures	Silk	37	41
	Hosiery.	77	62
	Wool	88	71
	Cotton..	113	73
	Dyers	110	98
Iron trades	Blacksmiths	72	74
	Ship-builders	88	77
	Iron manufactures	96	91
	Wagon works..	99	95
	Brass works	176	115
Building trades	Sawyer	46	66
	Carpenters	90	78
	Bricklayers	110	98
	Plasterers and paperhangers	113	119
	Slater, tiler	135	131

		Phthisis index, 1891.	Cancer index, *1911*, all ages.
Coal-miners	Staffordshire	44	133
	Lancashire	65	135
	Wales	69	142
	Durham, Northumberland ..	72	150
	Derby and Notts	74	*153*
	Yorkshire	*85*	*158*

(*d*) The same element of proportion is seen if a graph be prepared in which cancer in 1911 is plotted against phthisis in 1891. 95 per cent. of all the deaths are included in the occupations which fall within the area bounded by the lines which diverge at an angle of 12 degrees. It is possible that this angle would be less if the *phthisis index* could be built up from percentages of age-periods earlier than 25–35. The probability of chance becomes less as the angle becomes less. When the same occupations are plotted against phthisis *in 1911 the angle is 25 degrees.*

(*e*) By means of the percentage of cancer on the three youngest age-periods it is possible to foretell what the incidence will be in later life. The same factor decides the incidence in all the age-periods from 25 onwards. This rule is, I think, invariable and if established it almost precludes the possibility of chance. Take, for instance, the actual number of deaths from cancer in two *occupations* about equal in size in 1911—gardeners and clerks (commercial, law, bank, and insurance) (*Table VIII.*).

(*f*) A time element is found in the coördination of phthisis and cancer. *An inspection of the graph shows* that in 1891 all the occupations were nearer to the cancer base line than in 1911. *If* we could make a similar graph for earlier periods the dots would be still nearer this base line. In 1861 the cancer-rate in men was 220, as against 900 in 1911, and hence the factor which has determined the present rate of *increase* has apparently been in operation for about 65 years.

TABLE VIII.—*Deaths from Cancer in Gardeners and Clerks in 1911.*

Age-period.	Gardeners.		Clerks.	
	Quota.	Deaths.	Quota.	Deaths.
25–	9975	9	10,455	44
35–	9541	45	8830	102
45–	8951	162	7184	271
55–	*7993*	*324*	*5265*	*353*
65 to end.	*6230*	*639*	3155	303

(*g*) In men an increase in the cancer-rate of 17½ per cent. occurred in the five-year period 1881–6. This period was also marked by the first decided reduction in the phthisis-rates for men between the ages of 45 and 65.

When the three census periods are compared it is found that the reduction of phthisis and the increase of cancer has taken place by two methods. Some occupations have changed in both respects at a nearly *uniform rate, so that in a graph the three points are* joined by a straight line. In others a great reduction *in tubercle in the first ten years is followed* by a sharp rise in cancer in the second, so that the position for 1901 is the point of an obtuse angle. It is noteworthy that in very few cases is this a right angle, and in only two cases has there been an increase of phthisis between 1901 and 1911, so that the angle becomes less than a *right angle. In no case* whatever did a reduction in phthisis take place between 1891 and 1901 without an increase in cancer.

In the following group I presume that the reduction in phthisis has been a process which has occupied a longer time than usual. A great reduction in tubercle and a considerable increase in cancer had taken place by *1911, but I anticipate* that the sharp rise in cancer will be disclosed by the census of 1921.

Group F.—(34,707 deaths.)

Index 1891 : Phthisis, 1274; Cancer, 400
„ *1911* „ *780* „ *775*

Watchmakers and jewellers, toolmakers and cutlers, cabinet makers, cotton weavers, general storekeepers, booksellers, potters, bakers, teachers, tailors, drapers, private servants.

A small number of occupations, including about 12,000 deaths, have been rejected for a variety of reasons. Of these, the most important is the change of occupation which often occurs in a man's life-time.

In this investigation the deaths in each occupation have been treated as a self-contained unit of the population, which died out completely in the three years of the census period. No attempt has been made to connect them with the living members of the same occupations who filled in census papers. This method has given a high degree of uniformity to the results set out in this paper. For the last age-period, 65, the deaths from any given disease are expressed as a percentage of all the deaths after 65. For the next preceding age-period a quota is found by adding together all the deaths of the last two age-periods. The percentages are thus calculated on all the deaths which occurred after 55, and so on *for the earlier age-periods.* As an example, we may say from Table VI. that 4·88 per cent. of labourers over the age of 55 *died of cancer before they* reached the age of 65. The drawback of this method is the fact that in any year in which the *mortality* was excessive, as, for example, from influenza, all the percentages from cancer are too low, because the total number of deaths is excessive and the deaths from cancer are not *perceptibly* affected by influenza. *On the other hand,* the deaths from phthisis are greatly increased by influenza, and this percentage is higher than normal. This objection does not, however, apply to the comparison of occupations with one another at each census period, because they all have been in the same relation to any such disturbing factor. The Registrar-General's reports include deaths from 15 and upwards in each occupation, but the proportion of deaths in the *age-period* 15–25 is so variable to the total deaths in many of the occupations that I decided to begin with the age of 25. This compelled me to base the index for phthisis on age-periods which are probably too far advanced for the best results, because there are many indications that the age-period 10–25 is all important in regard to this disease.

I have given the data for phthisis throughout this paper, because other forms of tubercle are not set out in reports earlier than that for 1911; but in any case phthisis covers about four-fifths of the deaths and it is also the most important source of infection, so that it is possible that cancer rises and falls in relation to phthisis rather than to tubercle in general.

Significance of Cancer After the Age of 65.

With regard to the significance of cancer after the age of 65 the following points must be weighed. If these deaths are included in an estimate of cancer incidence during the whole life-time they tend to equalise the rate for all occupations. For the occupations with the *greatest proportion of deaths after* 65 are those which have the lowest incidence of cancer at all the other age-periods. Conversely, the occupations with the lowest proportion of deaths after 65 are those with the highest cancer-rates at all age-periods. The large numbers at the lower rate in the "best" lives more than balance the small numbers at the higher rate in the "worst" lives. In 1911 the cancer-rate for 65 + was about 10 per cent. in most occupations. There is no difficulty in the theory that more than 1 out of every 10 had become resistant to tubercle, even in such occupations as farm labourers. These considerations led me to close the index for cancer at the age of 65.

The foregoing results appear to be conclusive against the theory that cancer is simply one of the degenerations of old age, and that the present increase is due to the higher percentage of people that now reach old age. By the methods I have adopted it is easy to calculate the percentage that reached 65 in relation to the number that entered any given occupation at 25. If the occupations are grouped on this basis it is found that, in most cases, the higher the percentage that reaches 65 the lower is the cancer incidence at all age-periods. Thus, in 1911, 66·8 per cent. of the deaths in Group A were over the age of 65, while this percentage in Group E was 25·4. But the cancer-rate for Group E was higher than that for Group A at every age-period, whereas if cancer depended chiefly on old age the opposite should be the case. Again, if old age was the dominant factor we should expect the cancer-rate to increase steadily up to the end of life, as is seen in the deaths from cerebral hæmorrhage, but this is not the case. (Table IX.)

Table IX.—*Percentage of Cancer and Apoplexy in Men.*

Age-periods		55–	65–	75 to end.
Cancer	1911	4·7	6·7	6·1
	1921	6·0	8·6	7·9
Cerebral hæmorrhage	1911	2·4	5·2	8·0
	1921	2·2	5·3	9·5

There is perhaps an analogy between the two diseases in this respect. Apoplexy in early life may usually be explained by the presence of a predisposing factor which either raises blood *pressure or* weakens the wall of the vessel. Apoplexy late in life seems to have been common from the earliest times. Cancer at all ages over 35 has increased *so* much during the past 40 years that the disease *has* become a new problem in all civilised countries. This fact alone makes it probable that the old causes which produced a small number of cases in the past are now at work on a type of population that has been specially prepared for the disease.

Early Prevalence of Tubercle.

The history of tubercle in England shows that it was very prevalent during the early part of last century. In some localities hardly a family could be found which was not affected with the "strumous disposition." After allowing for some exaggeration in such generalisations there can be little doubt that the high figures of all the early annual reports are fully justified. With the marked improvement in food-supply and the slower amelioration of the other conditions recovery from a definite attack of phthisis would become more common. In some cases a high degree of immunity might be developed without the occurrence of a recognised attack of phthisis. Let us suppose that frequent contact with tubercle bacilli develops powers of resistance in the individual perhaps on lines similar to what is known to be the case in diphtheria and other diseases. If this resistance includes a quickening of the readiness to proliferation of cells in response to a special form of stimulus most of the facts discussed in this paper at once fall into line. The proliferation is seen in the typical epithelioid cells of the miliary tubercle. The development of powers of resistance to tubercle in people who did not succumb to that disease might thus form a predisposing cause of cancer in later life. The greater the percentage of phthisis in any occupation the greater the chance of any given individual either dying of the disease or else developing powers of resistance to it.

If phthisis acts as a predisposing cause of cancer I think it will be possible to a great extent to explain the difference in the history and incidence of cancer in women as compared with men. There are differences in the cancer-rates in different countries which may also be cleared up.

Further light on the relationship of cancer and tubercle may be obtained by reports on the family history of cancer patients. About 15 years ago Williams, of the Cancer Hospital, London, expressed the view that when several members of a family had died of phthisis the survivors were very apt to develop cancer. So far as I know no material exists at present for following up this line of inquiry. Post-mortem reports on cases of cancer should include a careful search for the signs of obsolete tubercle. Here, again, there are a few casual references to the association of the two conditions, but these do not cover a sufficient number of cases to be of much value. The facts I have brought forward may suggest lines along which a clinical test for early cancer may be worked out.

Finally, it should be possible to determine by experiment whether heightened resistance to tubercle has any effect upon the fate of transplanted cancer cells and upon the readiness with which irritation cancers can be produced. Under any circumstances cancer work is a slow and expensive process, but here is at least one definite problem the solution of which should be attempted without delay. The results of this statistical inquiry can be affirmed or refuted by experiment.

Clinical and Laboratory Notes.

BAKERS' DERMATITIS.

By N. Howard Mummery, M.R.C.S. Eng.,
MEDICAL OFFICER, MESSRS. J. LYONS AND CO., LTD.; MEDICAL DIRECTOR, FEDERATION OF MEDICAL AND ALLIED SERVICES; LIEUT.-COLONEL (LATE R.A.M.C.).

The intractable and relapsing skin eruptions commonly associated with the baking and confectionery trades have recently attracted considerable notice in both the medical and lay press, and, according to the report of the recent Conference of Operative Bakers and Confectioners published in the *Times* of August 10th last, the general secretary of their Union stated that there were 20 cases of bakers' dermatitis to-day where only one existed a few years ago. This may be true of some factories in Scotland and the north of England, but not, I think, of those in London.

In view, however, of this widespread interest in an industrial problem of much importance to employers and to their workpeople, it is possible that I may be assisting others, also engaged in seeking its solution, by making known the results so far attained in the course of investigations conducted during the past nine months in an up-to-date food factory. The investigations are incomplete, and doubtless some of the conclusions reached may have to be modified in the light of further experience and study.

These conclusions may be briefly summarised as follows:—

1. In spite of the opinions expressed at the meeting of the Section of Dermatology of the Royal Society of Medicine in October, 1924, it appears that there is a definite dermatitis to which persons engaged in factories manufacturing bread and pastry are peculiarly susceptible. It does not seem to be confined, however, to persons actually handling flour, dough, or sugar, but may, and does, affect workers in other departments of the same factory, thus suggesting that the causative agent may be carried in the dust of such factories. Certain mycelial fungus growths have, indeed, been cultured from this dust, but so far no definite connexion can be traced between these growths and those found in the skin lesions.

2. The skin lesion is primarily a vesicular eruption, similar in appearance to the sudamina or miliaria associated with obstruction of the sweat ducts, and is accompanied by intense itching, especially when the part is warm. That this irritation is due to distension of the vesicles is proved by the fact that it is immediately relieved by puncturing them. In the early stage the eruption is confined to the palmar aspect and inter-digital folds of one or both hands, the primary focus always being in the skin area most exposed to irritation or abrasion in the particular occupational process in which the patient is engaged. This primary vesicular lesion is rapidly followed by secondary lesions, the earliest of which are multiple fissures in the inter-digital spaces and on the dorsal aspects of the fingers. It quickly spreads at the periphery and, if not arrested at this stage, staphylococcic infection supervenes, and the condition then presents the clinical picture of eczema vesiculosum.

3. The primary vesicles contain a clear straw-coloured fluid. Microscopical examination of this fluid when obtained by aseptic puncture of the vesicles reveals the presence of numerous yeast-like mycelial growths.

4. The disease spreads by inoculation of abrasions in the surrounding area with the fluid from the original vesicles, these abrasions being caused, simultaneously with the rupture of the vesicles, by the scratching which the intense irritation incites.

5. The disease is communicable from one person to another by inoculation, which seems to take place through minute abrasions of the epidermis such as are common among manual workers. This is demonstrated by the fact that a small abrasion in the palm of my own hand, caused by a piece of stalk when rubbing up plug tobacco, became infected when collecting the fluid from a patient's vesicles, the same mycelial fungi being found in the vesicles which subsequently developed, although I had never handled flour or dough. I have kept this lesion "alive," though under control and confined to an area covered by a sixpenny piece, for eight months.

Prophylaxis.

As regards prophylaxis, my experience in a factory employing over 5000 persons, more than two-thirds of whom are directly engaged on food-producing processes, seems to indicate that the incidence of the disease can be effectually controlled by comparatively simple preventive measures. Those I have adopted—so far with conspicuous success, as in spite of the very large number employed only three persons are at present under treatment for this disease—are the following:—

(*a*) The exclusion as far as possible from dough and pastry handling of all persons with dry skins which render them liable to develop chaps and cracks in winter.

(*b*) Insisting that all minor skin lesions such as cracks, abrasions, and "hang-nails" are reported at once and treated with a solution of nitrate of silver or iodine.

(*c*) Weekly manicure on special lines, including the addition of "anosol" to the soap solution used for softening the finger-nails, for workers particularly liable to contract the disease.

(*d*) Providing all workers in contact with flour, dough, pastry, and sugar with a small towel suspended from a tape round the waist, these towels being collected and washed daily. The abolition of all "roller" or "common" towels.

(*e*) Supplying bowls of a weak, harmless antiseptic solution, such as sodium hypochlorite, in suitable positions in work-rooms, and encouraging employees to rinse their hands in this solution occasionally while at work.

(*f*) Every skin eruption, however trivial it may appear, has to be reported to the medical officer immediately, and any cases detected are suspended from duty and treated at the factory surgery until well.

Treatment.

After trying various methods of treatment I have found Metchnikoff's ointment (subchloride of mercury 33 per cent. in anhydrous lanolin) entirely satisfactory if applied freely, rubbed in, and covered to exclude air. When possible the evacuation of the vesicles greatly hastens healing. All cracks are painted with nitrate of silver, 15 gr. to the ounce of spiritus ætheris nit., before the ointment is applied. A case so treated in the early stage generally clears up entirely in a week, but, after resuming their ordinary work the patients continue to apply the ointment at night, when off duty, for a month or so in order to prevent relapses. Sometimes considerable patience is required to eradicate the disease, but the intelligent worker will at once report the appearance of a fresh vesicle which can then be evacuated antiseptically and aborted without further absence from duty.

I wish to acknowledge my indebtedness to Dr. Henry Semon and to Dr. Dennis Embleton for their help in the early microscopical investigations which have been carried out, partly by the latter and also in the fully-equipped biological laboratories at the firm's headquarters by Dr. L. H. Lampitt, F.I.C.

INTRADURAL ABSCESS SECONDARY TO FRONTAL AND ETHMOIDAL SINUSITIS.

BY H. ALEXANDER COWAN, M.R.C.S. ENG.,
REGISTRAR, ROYAL EAR HOSPITAL (EAR AND THROAT DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL).

THE following case presents a number of points of interest. There was long-continued nasal obstruction and nasal discharge for over 20 years, which were relieved by opening up the ethmoidal cells and removing the polypi. Rapid recovery followed, and the patient was quite well afterwards for six weeks. There was then a sudden development of signs of increased intracranial tension, all within 24 hours after the patient was readmitted to hospital. These signs pointed to abscess of the frontal lobe, and a frontal abscess was diagnosed, but post mortem no pus was found in the brain substance.

Clinical History.

A pale, thin man, aged 41, came to the out-patient department of University College Hospital on Jan. 8th, 1925, complaining of nasal discharge, nasal obstruction, and frontal headache. He said that he had suffered from nasal polypi for 20 years, and had them removed on several occasions. On examination his nose was full of polypi on both sides; transillumination showed both antra dark. He was admitted to hospital on Feb. 1st and operated on next day by Mr. J. F. O'Malley.

A large number of nasal polypi were removed from both sides of the nose, the ethmoidal cells being already opened up. The naso-frontal ducts were curetted with rasps to provide adequate drainage. Both antra were punctured and washed out, but neither contained pus.

The patient went home apparently quite well on Feb. 7th. He attended the out-patient department weekly and seemed much improved, and was progressing well. On March 26th, after a week of intensely cold weather, he came again to the out-patient department and complained of having suffered very badly from headaches for the past few days. He had a profuse nasal discharge, worse on the left side, his temperature being 101·4° F.

He was readmitted to hospital on March 27th and treated with inhalations and weak iodine irrigations. On April 1st he was extremely restless and made several attempts to get out of bed; he also appeared to have difficulty in speaking. At 1 P.M. he was completely aphasic and could not understand anything said to him. Later in the afternoon slight hemiparesis developed on the right side. At 6 P.M. he was seen by Dr. F. M. R. Walshe; he then had slight but definite right hemiparesis, face, arm, and leg being affected, and some ptosis and external strabismus of the left eye. He appeared unable to express himself in answer to questions and showed a considerable defect in comprehension of spoken speech. He was somewhat stuporose and inclined to be restless. An abscess of the left frontal lobe was diagnosed.

Operation.

An external frontal sinus operation was performed on the same evening by Mr. O'Malley; the sinus was found to be full of pus, but no track into the skull could be found. The lining membrane was very much thickened and the naso-frontal duct partially blocked, which was then opened freely into the nose. The frontal bone was then opened just above the superciliary ridge, and as soon as the dura was exposed it was seen to bulge. On incising the dura over an ounce of thick yellow pus poured out, which seemed to come from the frontal lobe, as this presented in the wound. Drainage was established with two rubber tubes placed side by side. A tube was also put through the frontal sinus and carried into the nose. Throughout the night the patient's condition became worse and he died the next morning.

Post-mortem Examination.—The following was the condition found. There was pus in both frontal sinuses, a large intradural abscess was on the left side, producing pressure on the left frontal cerebral cortex; there was also a collection of pus at the base of the brain. No cerebral abscess was found, but there was pus in the left lateral ventricle.

I must thank Mr. O'Malley for permission to publish these notes.

Reviews and Notices of Books.

INTERNAL SECRETIONS.

The Chemical and Physiological Properties of the Internal Secretions. By E. C. DODDS, Ph.D., D.Sc., M.B., B.S., Professor of Biochemistry in the University of London; and F. DICKENS, M.A., Ph.D., Assistant in Biochemistry. London: Humphrey Milford, Oxford University Press. 1925. Pp. 214. *8s. 6d.*

THE object of this small volume is to present a summary of the literature dealing with the chemical aspects of the internal secretions. This includes the methods for preparing active extracts, the isolation and purification of the active principles, a discussion of their chemical constitution, and of the various methods used for standardising the products. Up to now information covering these various points was scattered very widely throughout scientific memoirs and had to be sought for sometimes even in the files of the Patent Office. The work has been done with great care and a highly technical subject is presented in such a clear and interesting manner that it can be followed without difficulty even by those who are possessed of only an elementary knowledge of biochemistry. A bibliography is appended to every chapter and all the references given have been consulted personally by the authors.

The book begins with the internal secretion of the pancreas—insulin—and the insulin-like substances obtained from other sources. This is followed by the various active substances obtained from the anterior and posterior lobes of the pituitary—tethelin, pituitrin, histamine. The next chapter deals with the various active preparations obtained from the thyroid. A brief but very interesting chapter is devoted to the ovarian hormone. Here the authors state that they have succeeded in confirming the observations of Hermann and Frinkel and of Allen and Doisy, who obtained active preparations capable of inducing œstrus. A chapter is devoted to adrenalin, and the final chapter deals with secretin, the parathyroid glands, and spermine.

The title of the book is somewhat misleading in giving the impression that the physiological properties of the internal secretions have received the same careful and exhaustive treatment as the chemical properties. If this had really been accomplished the book would have had to be greatly expanded. As it is the authors have dealt in considerable detail mainly with those problems in which they are especially interested. Thus the action of insulin is subjected to a clear and detailed discussion, and the conclusion is arrived at that no adequate explanation has as yet been offered. Pituitrin is also treated fairly fully. But the sections dealing with adrenalin and the thyroid hormone are short and far less complete. The former begins with the statement that the most important property of adrenalin is its pressor effect; the latter opens with the remark that the most important action of thyroid tissue is its ability to restore cretins and myxœdematous patients to normal. If we mean by physiological properties the part played by hormones in the normal organism then the properties quoted would appear to be among the least important. The statement that adrenalin produces no effect upon the pupil unless the superior cervical ganglion is excised applies only to local application, and we should have thought that the effect of toxic doses of adrenalin was not indefinite as stated, but clearly to be seen in intense pulmonary congestion and hæmorrhage. The action of adrenalin on metabolism is discussed in a few lines and summed up in the remark that "little general effect can be found except the glycæmic reaction." But this reaction requires very massive doses of adrenalin, exceeding probably the amounts secreted under physiological conditions, and no reference is made to the extensive literature based on the work of Cramer, Boothby and Sandiford, Aub and his collaborators, and more recently of Cannon, which shows a general agreement to the effect that adrenalin increases the metabolism, raises the heat production, and is secreted as a physiological response to cold, contributing to the heat regulation of the body.

In the section dealing with secretin no mention is made of the evidence presented by Prof. Dodds himself some years ago to the effect that the formation of secretin by acid may only be an unimportant factor in pancreatic secretion. In the section on the parathyroids reference might have been made to the work of Dragstedt and of Luckhardt on the intimate relation of diet and the function of the parathyroid glands as well as to the recent striking therapeutic results obtained by Scott in sprue, since they have a bearing on the function of these glands in relation to calcium metabolism. These little shortcomings, as we have felt bound to regard them, do not, however, affect the main object of the book, and can be readily rectified on revision.

As a readable and reliable work of reference on the chemistry and biochemistry of the internal secretions the book is strongly to be recommended. Literally, to repeat the cliché, it fills a long-felt want.

DENTAL STUDY AND PRACTICE.

The Anatomy of the Root Canals of the Teeth of the Permanent Dentition. By WALTER HESS, M.D., D.D.S., Professor of Operative Dentistry in the University of Zurich. *The Anatomy of the Root Canals of the Deciduous Dentition and the First Permanent Molars.* By Dr. Med. Dent. ERNST ZÜRCHER, School Dentist of Zurich. London: John Bale, Sons and Danielsson. 1925. Pp. 199. 10s.

THE conception of the root canal of a tooth as a funnel-shaped space of simple form, extending down the root of the tooth, is still tacitly assumed to be correct by many dentists. Were this so the problem of filling the root canal of a pulpless tooth would be comparatively simple. The examination of teeth by histological and other methods, dating as far back as 1844, has shown that this conception is inaccurate. But until a technique could be elaborated which would demonstrate the exact shape of the root canals of the teeth by a cast of their interior, the dental profession was content to ignore the scattered observations of this branch of dental anatomy. Hess, following up the work of Preiswerck, Fischer, and others, has devised an ingenious method of obtaining a cast of the root canals by filling them with vulcanising rubber, such as is used for dentures, under pressure, and then vulcanising it so that it became hard. The tooth was then dissolved in acid, leaving a solid cast of the canals.

Using this method on a large number of teeth Hess has established the fact that the root canals of the teeth are of surprising complexity. They possess numerous branches, and, instead of terminating in a single apical foramen, frequently break up into a series of fine branches like the delta of a river. Accounts of this work have been published in this country and Hess's work confirmed by Parfitt and others, but the complete text with the original illustrations now receives translation for the first time. The bearing on operative technique is obvious. The problem of filling a root canal so completely that infection cannot penetrate, already difficult, now becomes intensified. Mr. W. H. Dolamore, in his preface, suggests that some method of impregnation by metallic silver, as advocated by Howe, may provide the solution of this problem. An interesting point brought out by Hess is that the canals tend to become more complex as age advances by a process of intra-canalicular calcification which forms partitions of dentine in the course of the root canal.

The book is illustrated by many plates (rather confusedly numbered) showing the various forms of canals met with in each tooth of the human series at different ages. It is a notable and important contribution to dental anatomy. The unnamed translator has done his work well.

Bacteriology for Dental Students. By R. B. HERVEY WYATT, M.A., M.B., Ch.B., D.P.H., Lecturer in Bacteriology at Birmingham University. London: Humphrey Milford, Oxford University Press. 1925. Pp. 134. 6s. 6*d*.

THE problem of teaching bacteriology to a student whose curriculum is already crowded is not easy to solve. Obviously the dental student should at least know the elements of the subject, and rather more than the elements of that part of bacteriology which is concerned with infections of the mouth. This book, written by one who is engaged in lecturing to dental students, is a successful effort to provide a short manual of the subject which, though elementary, yet covers the ground in a readable and accurate manner. The book is intended to accompany a practical course such as is undertaken by the dental students at Birmingham University. So used it should prove of value. The chapter on the bacteriology of the mouth might with advantage be extended beyond the 11 pages given to it. The dental student should know all there is to know about the bacteriology of dental caries and pyorrhœa. It would have been helpful if the author had reviewed the literature in more detail. The work of McIntosh, James, and Lazarus-Barlow is mentioned, but the later work of Kilian Clarke on the *Streptococcus mutans* is not referred to. It is curious that nowhere are Koch's postulates given. The book is well produced and the price moderate. It fills a distinct gap in dental literature.

The Mathematics of Dental Prosthetics. By F. W. Rapp. London: John Bale, Sons and Danielsson. Pp. 42. 5*s*.

SINCE the days of Bonwill a considerable amount of attention has been paid to the mathematical side of denture construction, and there is no doubt that dental prosthesis has benefited by the scientific principles enunciated. This little book is evidently written by one who has expert knowledge of the prosthetic side of dentistry. The author has devised a set of instruments which, he claims, will make for greater accuracy and increased efficiency. Mr. Rapp considers the problem of denture construction to be an engineering one, and in a sense this is true, for a denture to be stable and efficient must conform to certain mechanical principles. But the stresses and strains of a denture in any given mouth cannot be calculated exactly in the same way that an engineer can calculate them when using steel or concrete, for the tissues of the mouth differ in different individuals. In spite of the elaborate formulæ which have been worked out by various authors for constructing dentures, prosthesis still remains as much an art as a science. Rule-of-thumb methods often give excellent results, but sometimes fail where more scientific methods may succeed. The non-mathematical reader need not be daunted by the title of this book, for only an elementary knowledge of mathematics is subsumed, while the technique outlined by Mr. Rapp is not difficult. Though it will not solve all the difficult cases met with in practice, this technique is worth a trial.

FAIR WINDS AND FOUL.

A Narrative of Daily Life Aboard an American Clipper Ship. By FREDERICK PERRY. London: Martin Hopkinson and Co. 1925. Pp. 204. 10*s*. 6*d*.

MR. PERRY writes with first-hand knowledge, for he served in the American Mercantile Marine and worked his way up from being a "Rufus Hatch cadet" to being a mate in the Pacific Mail Steamship Company and the California Clipper Ships Company. The voyages described in this book are those made by him during the period of his service from third mate to mate. His description of the voyage of the clipper *Continental* from New York to San Francisco is as thrilling as any description of rounding the Horn that we have ever read. These descriptions usually are exciting, and Mr. Perry's narrative is worthy to stand beside Mr. Jack London's "Mutiny of the *Elsinore*" and Mr. Basil Lubbock's account in "Round the Horn" of life before the mast. The *Continental* took 172 days to make out her voyage and she took 21 days to make her westing, water ran very short, and on the 150th day out scurvy appeared. Off the Horn the *Continental* spoke the *Flying Dutchman*—at any rate some ship whose attributes were sufficiently mysterious to have gained it that appellation in less sophisticated days. Mr. Perry mentions that the captain believed scurvy to be contagious and isolated the four cases which first appeared, when no more followed, which confirmed him in his opinion. He tells a gruesome story of an English ship, the *Baltic*, which was towed just behind the *Continental* into San Francisco, having been 185 days out; the *Baltic* had 39 out of a total crew of 42 dead from scurvy, the only survivors being the captain, the carpenter, and the cabin boy. Mr. Perry's narrative is simply and clearly written, and he gives an excellent description of the rigging and sails of a clipper, which makes comprehension of his story fairly easy for a landsman. Altogether a very good book.

INTERPRETACION DE LAS APÉNDICITIS.

Indicaciones Operativas. By Dr. JUAN MARIÑOX. Barcelona: Libreria Medica y Tipografia. M. Rojo. Pp. viii. + 92.

THIS small volume, which is the prelude to a larger one, deals mainly with the author's own experiences, who, however, gives no statistics to show the extent of that experience, nor does he indicate whether it was derived from private or hospital practice. We note that he seems only recently to have encountered a case of perforated appendix without rise of temperature or pulse, though he is familiar with most forms of appendicular trouble. In the indications for operation the rules are not laid down with sufficient clearness, giving the impression that the author has not always the courage of his convictions. He states that the first attack of appendicitis unfailingly prepares the soil for future attacks which are usually of a much more dangerous character, but later he agrees with Sonnenburg that many of the gastro-intestinal disturbances in the first two years of life are appendical in origin but do not call for interference and leave no ill-effects. The truth is that appendicitis is rare at that age, but when it occurs in definite form it is very dangerous and requires prompt intervention. The author agrees with all surgeons of experience that the ideal practice is to operate in the first 48 hours, but apparently after that would, if possible, leave an abscess to be absorbed in the absence of urgent symptoms. He lays stress on the unexpected difficulties and dangers incurred when operating on quiescent cases, and quotes with apparent approval the surprising doctrine attributed to Roux that no quiescent case calls for operation until it has been free from active symptoms for two years. It is difficult to imagine that many patients, after being free from symptoms for two years, would willingly offer their abdomens to the surgeon's knife, while the author gives his countrymen a bad name for promptitude in that respect. In the subchronic cases (p. 82) —the "grumbling" appendices which are never really acute or really quiescent, but always a source of danger—it would seem hard to find a suitable moment for intervention, if this doctrine is correct. The accepted practice surely is not to give appendicitis a second chance where good reasons exist for suspecting it.

Dr. Mariflon's arguments, including the incontrovertible statement that exact diagnosis is impossible without opening the abdomen, all really tend to the same logical conclusion—viz., that in the absence of serious contra-indications every case should be explored. It is to be hoped that in a future book, which he forecasts, he will make his position clear.

JOURNALS.

QUARTERLY JOURNAL OF MEDICINE.—The July number contains the following articles: Four Cases of Congenital Dextrocardia, including a Case with Sino-auricular Block, by Leonard Abrahamson. All of the cases here recorded showed dextrocardia with complete transposition of the viscera. The article is illustrated by a series of electrocardiograms, one of which reveals a state of sino-auricular block.—Acute Ileocolitis in Children, by Robert Cruickshank. By ileocolitis is understood a condition in which diarrhœa is present, accompanied by toxic symptoms, and in which mucoid stools containing blood and pus are passed. Clinically it is indistinguishable from bacillary dysentery, but occurs sporadically in this country. The stools of 12 cases were examined and *B. dysenteriæ* of Flexner-Y type was isolated in seven. It is suggested that the most appropriate treatment is the administration of magnesium sulphate, together with injection of antidysenteric serum.—The Mode of Inheritance of Hereditary Ataxia, by W. Russell Brain. In hereditary ataxia it is probable that the disease depends on the presence of two Mendelian characters, one of which is a dominant and the other a recessive. The mode of inheritance cannot be explained on the theory that the disease behaves as a single Mendelian character, whether dominant or recessive.—Heredity in Polycystic Disease of the Kidneys, by H. W. B. Cairns. An interesting account is given of the occurrence of polycystic diseases of the kidneys in three successive generations of a family living in the East End of London. Myopia was also found to be present in many members of the family, either together with the polycystic disease or separately. The literature dealing with the hereditary transmission of the disease is considered and reference made to several of the published cases. The article is illustrated by a plate showing a polycystic kidney and a liver cyst obtained from the same case.—Critical Review: Cholesterol in Health and Disease, by J. M. H. Campbell. An introductory account is given of the physiology of cholesterol. Various points are discussed, such as the distribution of cholesterol throughout the body, the relationship of cholesterol to fat and lecithin, cholesterol and lipæmia, cholesterol in the blood during pregnancy, and in various pathological states as jaundice, gall-stones, nephritis, arteriosclerosis, diabetes, and anæmia. The influence of cholesterol upon hæmolysis and the rate of sedimentation of the red cells is also considered.

BRITISH JOURNAL OF SURGERY.—The July number (No. 49) is noteworthy in that in it a series of special articles dealing with pathological anatomy has been commenced. The Editorial Committee announce that it is the intention in these articles—which will eventually form an "Atlas of Pathological Anatomy" —to describe some of the most instructive and historical specimens in the Hunterian Museum of the Royal College of Surgeons of England and in other metropolitan and provincial museums. Illustrations will be both in colour and in black and white, with X ray pictures and drawings of microscopical sections. In this issue nine specimens of sarcoma of the long bones are illustrated and described. There can be no doubt that this series will be of the greatest interest, and of great value as a permanent and convenient record of many supremely instructive specimens.—Sir D'Arcy Power contributes his XVIIth Eponym on Charcot's Joints, in which he describes with much interest Charcot's original contribution.—F. G. Bell discusses at considerable length the characteristics of the teratoid group of testicular tumours.—A. C. Perry has investigated the after-results in 653 cases of operations for malignant disease of the breast. His conclusions are the result of careful analyses, and are worthy of notice.—G. P. B. Huddy, having collected four clinical and four post-mortem cases of urethral pouches, gives an interesting account of their pathology, symptoms, and treatment.—H. Morriston-Davies describes his technique in the operation of extrapleural thoracoplasty.—W. M. Carrick contributes a short note on the pyelographic appearances in cases of polycystic disease of the kidneys.—H. W. B. Cairns publishes some observations on the ætiology and treatment of cystitis.—A. F. B. Shaw and R. P. Smith report six cases of Reidel's chronic thyroiditis; in view of the acknowledged difficulty of accurate readings of thyroid histology, this is a valuable contribution.—In Vol. IX., 1921, 16 cases of surgical treatment of aneurysms of the aorta by wiring were reported, and now five others—three at length—are put on record. The three in detail are by H. M. Colt, C. J. Marshall, and C. P. G. Wakeley. The two former were aneurysms of the abdominal and the latter of the thoracic aorta. It is instructive to note that Colt's and Marshall's cases died of acute dilatation of the stomach, and the post-mortem examination revealed the sacs full of firm clot.—V. Z. Cope's Hunterian Lecture on Extravasation of Bile is here reported.—E. H. Shaw comments upon the pathology of 11 cases of carcinoma of the vermiform appendix.—R. O. Ward contributes a paper on 11 cases of vesical diverticula, dealing with their clinical signs and treatment.—W. E. M. Wardill reports a case of polypi in the bowel causing intussusception.—Sir Cuthbert Wallace has a short note on two cases of advanced carcinoma of the breast treated by the interscapulo-thoracic amputation.—The following short cases are reported:—T. B. Mouat: Two cases of polypus of the stomach. E. T. C. Milligan: Intussusception of small intestine through a fæcal fistula. A. Rendle Short: Case of von Recklinghausen's osteitis fibrosa. C. P. G. Wakeley: Ossifying chondroma of a rib mistaken for sarcoma. H. W. B. Cairns: Renal colic as a late complication of nephrectomy. S. Pringle: Cyst adenoma of pancreas. Arthur Evans and S. Cade: Ectopic ovary. H. Drummond: A case of heart suture Sir Hugh Rigby: Snaring of caput cæci and appendix by a band. W. Adams: Two cases of foreign bodies in the alimentary tract. F. G. Ralphs: Sarcoma of renal pelvis.

PUBLIC HEALTH ADMINISTRATION.

ADMINISTRATIVE MACHINERY IN EUROPEAN COUNTRIES.*

I. THE NETHERLANDS.

HOLLAND is a constitutional and hereditary monarchy; the legislative authority is laid with equal responsibility on the Sovereign and the Parliament, the latter consisting of an Upper and a Lower Chamber. Each of the 11 provinces has a Commissioner, nominated by the sovereign, and a representative body whose members are elected for four years. The representative body elects a permanent commission of six members to administer the common laws. The provinces are further divided into 1100 communes, each with its communal council, and an executive body called the Communal College, which consists of the burgomaster, elected by the sovereign, and from two to six aldermen, chosen from among the members of the college.

The public health administration, as organised by the law of 1920, is under the control of a Director-General of Public Health, who is directly responsible to the Minister of Labour for the activities of his department. The Ministry is advised by a Public Health Council, comprising some 15 subcommittees dealing with special departments: general and social health work, infectious diseases, general pharmaceutical work, pharmaceutical and chemical work with particular regard to preparation of commercial chemical products, feeding, hygiene of childhood, tuberculosis, alcohol, cattle and meat examination, "water, field, and air," medical assistance and nursing, venereal diseases, housing problems, statistical researches, and ankylostomiasis.

The country is divided into health inspectorial districts, each with its personnel responsible for the observance of public health regulations. There are also 134 health committees, chosen from local inhabitants, and appointed by the Provincial Governor. Neighbouring communes appoint a special doctor for the schools or engage one of the doctors residing in the district to fulfil the duties of this officer. At Amsterdam there is a communal medical and sanitary service with a director and several senior officers. At The Hague there is a communal medical service and a school medical service, each with its director. At Arnhem there is a school medical service, but no communal medical service. At Rotterdam and at Utrecht the two services are amalgamated. There are no provincial services. The Government intends to lay before the National Assembly a Bill regarding the health services as soon as circumstances permit. It has been proposed to appoint school doctors in each district, but this proposal has not so far been carried into effect.

There are no provincial disinfection services in Holland such as exist in Belgium. Provincial services now exist in certain provinces (Gelderland, Friesland, Groningen, Northern Holland, Overyssel, and Limburg), but they have been established by associations such as the "Green Cross" or the "White Cross"; there exist also certain communal disinfection services approved by ministerial decisions. These associations maintain disinfection services approved by the Ministry, and receive a fixed subsidy on this account in the same way as the communes. The State grants to the communes a subsidy of 50 per cent. of the cost of establishing, extending, and maintaining the disinfection service.

Organisation of Health Inspection.

Article 2 of the law on Protection of Public Health (1919) provides for the establishment of a Health Council to advise the Government in regard to any measures it may take to promote public health. Article 3 of the same law entrusts the duty of health inspection to (*a*) the principal public health inspectors; (*b*) the public health inspectors and officials assisting them; and (*c*) the Health Commissions. The Burgomasters have to send to the Inspector-General a monthly return of the deaths which have occurred in their communes, and they are also bound to inform as soon as possible the appropriate inspector of the departure, death, or if they are aware of it, cessation of practice of any doctor, dentist, or chemist or midwife in their commune. Health Commissions are established for each commune which contains more than 18,000 inhabitants. Several communes, the joint population of which does not exceed 40,000, may have a Health Commission between them. The expenses of these Commissions are borne by the commune, but the salaries of their secretaries are paid by the State Treasury. The decisions of the communal councils regarding matters of public health may only be promulgated, supplemented, modified, or repealed if the Health Commission established by the commune has been consulted.

Members of the Health Council are entitled to enter all public buildings, schools, factories, hospitals, &c., throughout the kingdom in order to see that the law is properly applied, and to enter places of residence to obtain information regarding the state of such places. Members of the Local Health Commissions have the same rights within their respective district only.

Registration.

The statistical work is organised by a Central Bureau of Statistics, established in 1899. The bureau publishes at regular intervals information regarding the population, births, deaths, and notifiable diseases. Registration of births, deaths, and marriages is compulsory, and the system is based on the Code Napoléon. The declaration of a birth must be made within three days, and must include hour and place of birth, names and address and profession of both parents, name, address, profession, and age of the declarant and two witnesses, religion of parents, and time and place of their marriage. "Stillborn" children include premature infants and those dying before registration. The Communal Registrar is the sole competent authority for authorising burial and the death must be certified by the medical practitioner. If death occurred without medical attendance, the body has to be seen by the "médecin de l'état civil." Information required on the certificate includes names, age, address, civil status, religion and occupation of the deceased, of the husband or wife, of the declarant, and the place of death.

Both with births and deaths certain communes ask a larger or smaller number of further questions for statistical purposes. The information relative to infant mortality is remarkably complete.

II. BELGIUM.

The kingdom of Belgium, the most densely populated country in Europe, is an independent constitutional monarchy, and is divided into nine provinces, each having a governor, nominated by the King, and a Provincial Council, which is partly elected every four years and partly a permanent standing committee of six members. There are 41 arrondissements, which are groups of communes under Commissioners, each of the 2638 communes having self-government in all local matters, and comprising a burgomaster, nominated by the King, an elected council, and an executive "college," selected from the council.

The laws controlling public health administration fall into three main groups: (1) Those giving the National Government, provinces, or communes power to issue regulations within defined limits; (2) those specifically enumerating the rules and regulations that are to be observed; (3) certain international conventions.

The central public health administration is part of the functions of the Ministry of the Interior and of Hygiene, which has two quite separate divisions, the Administration of Public Health and the Central Statistical Department. There are also various technical services and advisory bodies.

---

* Based on a Series of Reports on National Health Organisation to the Health Section of the League of Nations and on Statistical Handbooks prepared by the Section. Obtainable in Great Britain from Constable and Co.

Seventeen provincial medical commissions exercise a supervision over medical practitioners, midwives, and dentists, and are responsible for the observance of regulations relating to public health. Provincial inspectors of hygiene have recently been appointed, with wide executive responsibilities and duties. They visit and advise local administrations as to their obligations and public health interests, and inspect the services or institutions within the jurisdiction of local sanitary authorities. They forward monthly reports to the central administration dealing with their work, and special reports after any inspection which has reference to the sanitary condition of a particular area or the outbreak of a serious epidemic. Such reports include the results of laboratory investigations, prophylactic measures, and the tracing and disinfecting of carriers. The inspectors also forward every ten days summaries of all notifications received, with a short summary of the state of the public health in their area. Laboratory and disinfection services are reported on monthly.

The provincial authorities provide certain technical, laboratory, and disinfection services. Certain communes combine for public services, such as water distribution and hospitals, but there is no district arrondissemental public health administration. All communes that have three doctors or two doctors and a pharmacist have local medical commissions similar in their activities to the provincial medical commissions controlled by the central health administration. There are hygiene services in some of the towns and larger communes.

Statistical Work.

Every commune maintains registers of population, births, deaths, and marriages, and returns to the Central Statistical Department the basic tabulations from these registers. Births must be registered by the father, or other person present, before two witnesses, at the *mairie* within three days. In the towns and some of the communes there is a system of verification, whereby the father notifies the mairie within 24 hours, the official notifies the local "médecin de l'état civil," who visits the home to verify the data, fills up the certificate, and hands it sealed to the father, who then makes his declaration at the mairie within three days. "Stillborn" children include also those dying before registration—i.e., within three days of birth. They are recorded in a special register, separate from the ordinary births or deaths register. Deaths are notified by the nearest relative to the "officier de l'état civil," who is the sole competent authority to authorise burial. The registrar visits the house to satisfy himself that death has occurred, although in larger communes he delegates this duty to a "médecin de l'état civil." In some cases the certificate of the attending physician is accepted in lieu of this visit. Certification of the cause of death is not compulsory, but medical practitioners and other persons having knowledge of the cause of death are urged to give this information to the authorities. There is no system of medical verification of these particulars.

III. SPAIN.

The kingdom of Spain, with a population of 21 millions, is a hereditary and constitutional monarchy, the legislative authority being exercised by the sovereign in conjunction with the two houses of the Cortes. There are 49 provinces under their respective governors, who act under the direction of the elected provincial council. The council meets yearly, and is represented by a permanent "standing committee." Each commune has its own elected council, with a mayor, who acts as chief executive officer and justice of the peace. Neither the executive nor the Cortes may interfere with the provincial, communal, or municipal administrations, except when such authorities exceed their legal powers to the detriment of public interests.

The responsibility for the organisation of general health services rests on the General Health Department of the Ministry of the Interior, under a Director-General of Public Health. The four main sections are:

1. *The Section of Public Sanitary Institutions.*—This controls such health institutions as the National Institute of Hygiene of Alfonso XIII., the general sanitary epidemics organisation, and the special institutions for combating particular diseases—e.g., tuberculosis, cancer, malaria, leprosy, &c.

2. *The Health Section of the Interior.*—This section, under an inspector-general, controls and directs the activities of the 49 provincial inspectors, and also the medical, pharmaceutical, and veterinary services of the kingdom.

3. *The Health Section of the Exterior*, also under an inspector-general, is responsible for all sanitary measures at ports and frontiers.

4. *The Administrative Section* concerned with general measures.

The statistical office of the department compiles vital statistical data from the material received.

In each province there are sanitary corps, maintained by a 2 per cent. levy on each municipal or communal budget. Municipalities generally have their own municipal officers paid from municipal funds. Catalonia has a specially adapted health service of its own, combining under one administration the public health activities of the four Catalonian provinces.

The Royal Decree of March 8th, 1924, issued and signed by the Military Directory, provided for the reorganisation of municipal services and outlined their responsibilities towards public health matters, i.e.:

In Towns of not more than 15,000 Inhabitants (Art. 201).—Supervision of all drinking water; disposal of waste matter, excreta, &c.; inspection and improvement of dwellings, prohibition of insanitary habitations, &c.; sanitary supervision of public highways, stables, slaughter-houses, markets, lavatories, baths, and cemeteries; supervision and improvement of cesspools and prohibition of their use where they prove to be insanitary; inspection of schools and school-children; control of infectious diseases and measures to combat the outbreak of epidemics; vaccination of all children before the age of six months; revaccination of population where necessary.

In Towns of over 15,000 Inhabitants (Art. 204).—Removal of cesspools and gradual substitution of modern systems for dealing with waste matter and excreta; census of dwellings under direction of municipal medical officers of health; organisation of pure water-supply which will provide a minimum of 200 litres of pure water per day per person.

In Towns of over 30,000 Inhabitants (Art. 205).—Provision and maintenance of a municipal laboratory for the analysis of foods, drinks, drugs, and similar products, and for other duties in the interests of the inhabitants. Establishment of one or more disinfecting stations for beggars, &c., and one or more free bath-places.

In all Towns over 15,000 Inhabitants (Art. 200).—Compulsory vaccination against small-pox, provision of adequate services for combating outbreaks of infectious diseases, especially typhoid and typhus fevers, diphtheria, infantile cholera, trachoma, and tuberculosis.

The statistical work is under the control of the Director-General of Statistics, who is advised by a General Council of Statistics. Registration of births, deaths, and marriages is compulsory, and the magistrates of each commune are responsible for the custody and maintenance of the registers, the records being forwarded monthly to the Provincial Statistical Bureau. Births must be recorded within three days by the father or other person present at the time, with the age, profession, and nationality of the parents. The registration of stillbirths has been obligatory since 1919, and must be effected within 24 hours. "Stillbirth" includes babies dying within 24 hours of delivery. Deaths must be declared within 24 hours, accompanied by a medical certificate authenticating the fact and cause of death. In the event of sudden, accidental, or violent death a post-mortem examination is made by the judicial medical officer, usually assisted by a private practitioner.

(To be continued.)

Reports and Analytical Records.

B.D.H. CAPILLATOR.

(BRITISH DRUG HOUSES, LTD., 16–30, GRAHAM-STREET, CITY-ROAD, N. 1.)

THE pH value is a number used to express the active acidity or alkalinity of any fluid, the pH of pure water at 18° C. being taken as the standard of absolute neutrality, where the figure is usually given as 7. *The concentrations of H and OH ions here are exactly* balanced, and the balance will be upset by the addition of any acid or alkali. The colorimetric method is the most widely used one for determining pH values and in the hands of those who understand the procedure the technique is comparatively simple, little apparatus being required and the test taking practically no time. The *British Drug Houses have submitted* to us a pH capillator which provides an improved method. The capillator consists of a white card on which is mounted a series of capillary tubes in which buffer solutions containing an indicator are sealed. *The tubes are mounted three together, thus forming* a series of strips of colour, each strip being about ¼ in. wide and marked with its exact pH value. The series of colour standards on each card covers the complete colour change of the indicator. The determination of pH is carried out by using a capillary tube as a pipette and measuring by this means *equal quantities of the liquid under examination and indicator, mixing the two in a small watch-glass,* and then drawing the mixed liquids back into the capillary tube. The colour of the mixed liquids is then matched against the "Capillator" standards. Owing to the small quantity of fluid required for a test (one drop is sufficient), the capillator is invaluable *for the determination of the pH* of such liquids as urine, saliva, tears, plant juices, and innumerable other organic fluids. Another advantage of the capillator method is that the pH of slightly coloured fluids may be determined directly without the use of any compensating device, such as is necessary when using test-tubes for comparison purposes. Owing to the very thin layer of liquid in the capillary tubes, the inherent colour of urine and other similarly coloured liquids is negligible. To *determine* the pH of any liquid, it is necessary first of all to choose a suitable indicator. A preliminary test is made with B.D.H. universal indicator, the range of which is from 3·0 to 11·0; thereafter a suitable particular indicator is chosen, such as, say, thymol blue (pH 1·2–2·8), bromo-cresol purple (pH 5·2–6·8), or phenol red (pH 6·8–8·4), *and the accurate estimate* is thus made. The compactness of the capillator is such that a complete set comprising nine or ten colour standards of *an* indicator occupies a space of only 3 in. by 4⅝ in. by ¼ in. It is thus possible to carry in the pocket a number of capillators of different indicators covering a large range. This valuable *modification of the colorimetric* method is due to Dr. Henry A. Ellis.[1]

KHARSULPHAN.

(BURROUGHS WELLCOME AND CO., SNOW HILL BUILDINGS, LONDON, E.C. 1.)

In order to simplify the treatment of syphilis by the administration of arsenobenzol compounds, Kharsulphan has been manufactured under the licence of the Board of Trade and biologically tested under arrangements approved by that Board, while the Ministry of Health authorise the use of the preparation under the Public Health (Venereal Diseases) Regulations. The preparation is intended for subcutaneous and intramuscular injection only, and its advantage is that no elaborate technique is required either in preparing solutions or in making injections. The dose is simply dissolved in 1 c.cm., or *more, of saline or distilled water in the barrel of the* syringe and is then ready for immediate use. The dose for each patient must be prepared separately as required, and on no account be stored or allowed to stand. It is readily soluble and there need be no delay in preparing individual doses. For subcutaneous *or intramuscular* injection the commencing dose *should be 0·15 g. and the following range of doses is* given. Men, 0·15 g. to 0·6 g. (approximately 2–9 gr.); women, 0·15 g. to 0·45 g. (approximately 2–7 gr.); children, 0·15 g. to 0·3 g. (approximately 2–4 gr.); infants, 0·05 g. (approximately ¾ gr.). In intramuscular injection strict asepticity must be observed. The skin should be painted with iodine, and the *syringe and needle boiled for five minutes in a* 5 per cent. solution of carbolic acid. Treatment should commence with small doses at intervals of two or three days and as the dose is increased the interval should be lengthened. It may have to be continued for many months. The drug is contraindicated in cases of advanced visceral disease, and caution *is necessary in* cases of arterio-sclerosis, diabetes, advanced nervous disorders, and certain skin diseases.

CREAM OF NUJOL.

(ANGLO-AMERICAN OIL COMPANY, LTD., ALBERT-STREET, CAMDEN TOWN, N.W. 1.)

The properties of Nujol have been brought before our readers in these columns on previous occasions. We have now received from the firm a new product, Cream of Nujol, in which Nujol is combined with *agar-agar for use in constipation.* The preparation contains no cathartic ingredient, saccharin, or sugar, and therefore can be prescribed with *safety for obese* or diabetic patients, and others where anything like active purgation would be harmful. The preparation is directed to the needs of those with intestinal stasis particularly in atonic form, and it can be employed over extended periods in obstinate cases without risk. It can be diluted with milk or water if it proves *more palatable in this manner,* and the emulsion is pleasantly flavoured.

NOCTAL.

(W. DEDERICH, LTD., STANLEY HOUSE, DEAN STANLEY-STREET, WESTMINSTER, S.W. 1.)

Messrs. Dederich, Ltd., are the agents for the firm of J. D. Riedel of Berlin, from whom we have recently received for clinical trials a preparation of isopropyl barbituric acid termed noctal. We are informed that the clinical experiences of the specific under the hands of Berlin physicians have been satisfactory. Noctal is supplied in tubes of ten tablets of 1 gr. each, the dose being *from one to* two tablets.

MEAD'S RECOLAC.

Messrs. Mead, Johnson and Co. ask us to correct a statement made in our issue of June 6th in this column with reference to the above preparation, that "full instructions how to prepare these foods are issued with the preparation." The company say *that their* "*policy does not* permit them to issue directions on or with their foods to the general public, as directions are only supplied to the medical profession, and for their prescription only." Our note referred, of course, only to the position as between the company and our professional readers, and we learn that feeding instructions will be gladly supplied to doctors through the distributors: Brooks and Warburton (A. D. S. Co.), Ltd., 40–42, Lexington-street, London, W. 1.

TILBURY SEAMEN'S HOSPITAL.—Since the new wards were opened towards the end of June the daily average number of in-patients has increased by nearly 50 per cent. A unique feature of the hospital is a separate wing exclusively for the treatment of Indian seamen, which was provided by the generosity of Mr. P. G. Singhanee, of Poona, who gave a lakh of rupees for the purpose.

THE CLAYTON ANILINE CO., LTD.,

Pharmaceutical Department, 68½, Upper Thames St., London, E.C.4,

have pleasure in announcing that they are in a position to supply

PYRIDINE - ß - CARBONIC ACID DIETHYLAMIDE,

the new, water-soluble, analeptic with a camphor action, and which was the subject of an article by Prof. E. Stanton Faust, published in *The Lancet*, June 27th, 1925, under the name of

CORAMINE

Indications

Shock, heart asthenia following infectious diseases (pneumonia, etc.), arteriosclerosis, renal affections, bronchial asthma, emphysema, poisoning through narcotics, asphyxia of the new-born, etc.

Packages

Ampoules (1.1 cc.) for hypodermic and intravenous use, boxes of 5, 20, & 100.

Liquid for oral administration, vials of 15 cc. and 100 cc.

REPRINTS OF PROF. FAUST'S ARTICLE WILL BE SENT TO PHYSICIANS ON REQUEST.

AN EMPIRE PRODUCTION

OF GREAT VALUE TO THE INVALID

Burgoyne's Tintara

OBTAINABLE OF ALL WINE DEALERS

Sample Bottle sent free in the United Kingdom, on receipt of professional card.

Ferruginous.

THIS PURE AUSTRALIAN WINE was introduced in 1871, it has been highly recommended by the Medical Profession in all cases where strength and nerve force have required building up. In anæmia, debility, neurasthenia and in convalescence after any illness, this full-bodied, generous wine, palatable as well as health producing, has proved itself the finest of all natural stimulants.

P. B. BURGOYNE & CO., Ltd.,
Burgoyne House, Dowgate Hill, London.

'Byno' Hypophosphites

Trade Mark

An efficient Digestive, Tonic and Restorative

Invaluable in retarded convalescence and asthenic conditions generally.

In 'Byno' Hypophosphites are combined the tonic qualities of the Nux Vomica and Cinchona alkaloids, the restorative value of the mineral hypophosphites, and the nutritive and digestive powers of 'Bynin' Liquid Malt, which is the basis of the preparation.

'Byno' Hypophosphites has for long been prescribed with great success in convalescence after acute infections and following surgical operations; in nervous and mental conditions due to overstrain or exhaustion; as an adjunct in the treatment of tuberculosis; in asthenia of the aged, and in a diversity of conditions where a general tonic and digestive is indicated.

COMPOSITION:

Calcium Hypophosphite	2 gr.	Iron	¼ gr.	Nux Vomica Alkaloids (equal to Strychnine)	$\frac{1}{16}$ gr.
Potassium	2 „	Manganese ...	¼ „	'Bynin' Liquid Malt ...	1 oz.
Sodium	2 „	Cinchona Alkaloids	1¼ „		

Further particulars and free sample will be sent on request.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 26, 1925.

THE PROBLEM OF THE MENTALLY DEFECTIVE.

THE Commissioners in Lunacy, one of the most valuable governing bodies in this country, have just issued their eleventh annual report, that is to say, the Report of the Board of Control. It is, as usual, full of useful information, and bears abundant witness to the keen industry of the Commissioners and their inspectors. Many of the points dealt with have been touched on in previous issues of THE LANCET.[1] The most important feature, however, of this report is the section on mental deficiency. The Commissioners apprehend a grave danger to the country unless the local authorities, and with them the general public and all governing bodies who bear the responsibility for defectives, regard their duty towards these unfortunate people very seriously, and put forth the utmost exertions to deal with their plight. The problem, like all national problems, is many-sided, but its two gravest aspects are undoubtedly, first, the provision of institutional accommodation, and, second, the coöperation towards one end of the four bodies who deal with mental defectives. On the whole, the local authorities are very active in their duty of ascertainment, and last year they discovered 12,300 new cases. Their returns, however, show that of those notified by local education authorities, 2197 remained undealt with at the end of the year, and that 1193 otherwise ascertained are still "subject to be dealt with." No action has yet been taken in these 3390 cases and the reason that suggests itself to the Board of Control is significant enough to rouse the most apathetic. Local authorities are disheartened by their constant inability to obtain vacancies. Some have applied in vain to 30 or 40 institutions—one, in fact, to 156—without success, and it is hardly surprising that efforts should at last be given up.

The provision of colonies for mental defectives was seriously hampered by the war, but many of the restrictions have since disappeared, and the Board of Control is always eager to consider well planned schemes. This is the only real solution—that every local authority should at once do its utmost to purchase a suitable estate and found a colony for its mental defectives. "Existing institutions," say the Board, "are full, and local authorities can no longer rely on charitable institutions or on the Poor-law for this provision. Unless, therefore, they give immediate consideration to this matter the beneficent intention of the Mental Deficiency Act will be hampered and will almost cease to operate. We take this opportunity of making an urgent appeal for immediate action, and we do so the more confidently because every year reveals clearly the terrible consequences of the neglect to afford this means of protection." These are strong words uttered by those who are best qualified to speak on the subject. Let us hope that those to whom they are addressed will see their truth and act on them. Many authorities have already done so, and the names are given of 20 who have colonies in existence, six who have purchased estates, and 17 who are taking steps towards this provision.

The second need, that of real coöperation between different governing bodies, is almost as urgent as the first. Besides the local authorities, who are the mental deficiency committees of the county or county borough councils, three others come into contact with defectives. They are the committees of mental hospitals, the staffs of H.M. prisons, and the governors of industrial schools and reformatories. The Board of Control points out that there are three ways in which coöperation between medical officers would greatly help towards the efficient control and care of mental defectives. One is that the medical officers of the local authority and the local mental hospital should meet and visit together the institutions for which each is responsible. It is the Board's policy to withdraw gradually all defectives from mental hospitals, beginning with children and young persons, and this policy would be much simplified if the understanding between these two departments were more complete. The melancholy progress of defectives in and out of mental hospitals, with intervals in prison or the workhouse, would become considerably rarer. A second way is for the medical officers of the local authority and those of the prisons to confer and visit one another's institutions. The wider range of study of mental deficiency which is available in a certified institution would be an advantage to prison medical officers, while the county medical officer might find in prison many types of defectives with whom he may have to deal on their discharge. Many forms of deficiency may be recognised by one authority and not by the other, and interchange of histories and free consultation would be of the utmost value. Thirdly, if the managers and medical officers of industrial schools and reformatories met the local authorities and their medical officers, the latter could take over young defectives and give them the protection and training without which they would certainly sink into pauperism and crime. A break in care and supervision, especially in early youth and adolescence, has led to periods in prison or in Poor-law institutions which are harmful to the defective, and render him less amenable to kindly control when he comes at last into an institution or a colony for defectives.

We have mentioned two only of the manifold facets of this vital problem; the others will be found in very great detail in the report itself. The present administration of the Mental Deficiency Act is a dark shadow on the social life of our country, and we shall be gravely at fault if we do not do our best to improve matters. We are fortunate in that our advisers and judges in this matter are as conscientious and as determined as this report shows them to be.

LONDON WATER.

MOST large cities now draw their water from unpolluted sources, some of them having laid hundreds of miles of aqueduct to remote and rainy mountain slopes. London has been content to drink from its own watershed, and after taking what is available from deep borings down to the chalk to obtain the remainder—being much the greater part—from three rivers, the Thames, the Lee, and the New, all highly polluted by human excreta. The labour involved in purifying this water is enormous, and to ensure safety constant vigilance is demanded from the Water Examination Department of the Metropolitan Water Board, which came into existence in November, 1905. SIR ALEXANDER HOUSTON, in his Nineteenth Annual Report to the Board[1] sets out the results of the chemical and bacteriological examination of the London waters for the 12 months ended March 31st, 1925, but although the results are duly set out as stated, the Report is much more than that, for HOUSTON has become the champion of London water as an abundant, cheap, safe, and palatable beverage, and his account of the doings of the Board becomes more and more of the nature of an epic. The opening of the great reservoir at Littleton by the KING on June 13th occurred since the period covered by the report, but HOUSTON foreshadows the value of increased water storage to the health of London. The reservoir doubles the storage capacity for Thames water and provides effectively against periods of drought. Procrastination facilitates enormously the purification of river water, and in this instance saves both time and money. The amount of solid matter contained in untreated Thames water is round about 100 pounds per million gallons, but in flood time it is still further increased, and during one January week in 1924 a ton of solid matter would have entered the Board's reservoirs with every four million gallons of water unless it had been possible temporarily to close the intake. The Littleton reservoir affords tremendous relief, for when full it would, in HOUSTON'S words, supply the whole world with a gallon of water per head for three days. These great settling tanks afford the opportunity of adequately sampling the London water before filtration, and the examination of the pre-filtration water goes on steadily. The loss of vitality to pathogenic microbes has now been correlated with certain physical, chemical, and bacteriological changes which occur in river water as a result of adequate storage, and it has become increasingly possible to deduce the margin of safety previous to liberation. The influence of time in destroying the vitality of pathogenic bacteria is well known to bacteriologists, and the new storage increases this safety period.

---

[1] THE LANCET, 1921, ii., 723.

[1] London: P. S. King and Son. 15s.

In the opposite direction of rapid purification the work of the Water Examination Department goes steadily on. The country owes much to HOUSTON'S determined advocacy of chlorination as a safe and ready method of purification. Recently the matter has been carried one stage further in an exhaustive test of super-chlorination with subsequent dechlorination. The advantages of this process are that, even with a very short period of contact, sterilisation can be made effective and serious taste troubles avoided. A drawback is the constant supervision required which lays added responsibility on the staff. The average dose of chlorine now used for Thames river water is 1 in 2·3 millions, and, so treated, 78 per cent. of the samples passed the test of containing no colon bacilli in 10 c.cm. of water. In regard to taste troubles, HOUSTON is content to remark that two million people have used this chlorinated Thames water since May, 1916, and he has not heard a single complaint. The New River supply has now been chlorinated for the sixth consecutive year, taste troubles having been avoided by skilfully contrived doses of chlorine and permanganate. Now that Mr. B. A. ADAMS'S work has succeeded in tracking down the iodoform taste of chlorinated water to atmospheric impurity, it looks as though the problem is within sight of complete solution, and, as HOUSTON puts it, the bogy of taste will before long largely be eliminated.

The Report contains much else of value and interest. In one section HOUSTON sets out a simple test (quaintly called "the three-star presumptive test") for colon bacilli in drinking water which gives reasonably accurate results under conditions of extreme simplicity. The Water Board is interested in living organisms other than bacteria in relation to the Thames. HOUSTON still regards the Thames as a salmon river in a potential sense. The water at Hampton is well aerated at all seasons of the year; it is only in the lower reaches that no oxygen remains to maintain the possibility of fish life. Were it possible even temporarily to purify the tidal portion of the Thames during the descent of the smolts and ascent of the salmon, there is nothing in the state of the upper river to render salmon life impracticable. This is a great aim which not only keen fishermen may hope to see realised within their lifetime. Birds are not considered desirable visitors at the reservoirs. Gulls, so far as is known, do not suffer from the water-borne diseases that afflict human beings, but their droppings interfere with chemical control of the water. Considerable attention has been paid during the year to frightening gulls away from the West Middlesex works and other wild fowl from the aqueduct at the East London Works. But there is no page in the Report which does not contain interest for some class of reader, and we express again cordial regret that the Report is issued in the foolscap form so dear to precedent and so inimical to circulation. Every householder ought at least to read HOUSTON'S repeated declaration that drinking water should be obtained direct from the rising main and not after a more or less protracted sojourn in a tank in the roof. And he should see that he gets it.

◆

A CONFERENCE ON DRUG STANDARDS.

THE first international conference on the standardisation of biological products, which was held at Edinburgh in July, 1923, under the auspices of the League of Nations Health Organisation, adopted a programme of research into the best methods of testing various drugs and selected a certain number of laboratories in different countries where these methods could be investigated and the results compared. The National Institute for Medical Research of Great Britain was used as a clearing house for the investigation and correspondence this work entailed, and a second conference, under the presidency of Dr. H. H. DALE, of the Institute, has just been held at Geneva to review the work of the past two years. The main subject of discussion was the standardisation of such products as pituitary and thyroid extracts, insulin, digitalis, salvarsan, and ergot, and the conference attained in the end a remarkable degree of unanimity. For digitalis, pituitary extract, insulin, and salvarsan a system of international standards was agreed upon; the iodine content was considered sufficient index of efficacy in thyroid extract, and the questions of ergot, extract of male fern and other vermifuges, and the vitamin-content of cod-liver oil, were held over for further investigation. The article by Prof. J. C. DRUMMOND, on p. 679 of our present issue, indicates the wide limits within which the vitamin-content of cod-liver oil may vary. It is probable that a separate specialist conference will investigate vitamin standards. The discrepancy which at present exists between one preparation of pituitary extract and another is shown by the fact that in one country, where control conditions are particularly good, a series of commercial preparations showed a range of activity of from 1 to 80. At the conference it was decided that the dry (acetone) extracted substance of the fresh posterior lobe of the pituitary recommended by Prof. C. VOEGTLIN to the Edinburgh conference should be adopted as standard. The Health Organisation of the League will be responsible for the distribution of small quantities of this preparation which will form national standards; the physiological activity of ⅛ mg. of the above preparation is to constitute a unit of activity, and preparations should be labelled according to their potency. Insulin has from the first been relatively well standardised owing to the action of the Toronto committee who introduced it; but different workers have got optimal results with different methods, while variations in animal reaction and in climate have led to widespread discrepancy between units as determined in different countries. A dry, stable preparation of insulin hydrochloride, which has been made at the National Institute for Medical Research, London, has been accepted as the standard, and a unit of insulin, corresponding to that biologically measured by the Toronto committee, is now defined as the physiological activity of ⅛ mg. of the standard preparation. The international standard of digitalis is to be a dry powder of the leaves of *Digitalis purpurea*, similar to that proposed at the first conference. Experiment on cats is to define the activity, and further methods will be investigated; it is arranged that the standard shall be distributed internationally, and its activity will be annually controlled. The subject of salvarsan is of special interest, because the patents governing its production and that of its most important derivatives expire in the course of a few years, after which any factory in the world will be free to make them, and may flood the markets, legitimate and illegitimate, with products of widely varying toxicity. Standards for these substances are to be prepared and deposited in the original laboratory at Frankfurt, just as the standard samples of antitoxic sera are kept at the Copenhagen Serological Institute, those of pituitary extract at Washington, and those of insulin in the Hampstead Institute.

THE LATE SIR FRANCIS DARWIN.

REFERRING in 1912 to "The Life and Letters of Charles Darwin," Sir Charles Sherrington remarked that "by the vivid presentation of the life, character, and work of one of the greatest naturalists the world has ever seen, by the modest self-effacement of its author, and by its literary charm, it has undoubtedly had a quickening influence on the advance of science in modern times." Sir Francis Darwin will perhaps be remembered best by this admirable biography of his father, with whose later work he was most intimately connected. Although he graduated in medicine while at St. George's Hospital, he never practised, but returned to his father's home at Down, where for eight years he acted as assistant and secretary. His name appeared on the title-page of Charles Darwin's "Power of Movement in Plants," and later at Cambridge he devoted much of his energy to research on the same subjects and provided a wealth of experimental evidence justifying the idea of the localisation of sense organs, which is now generally accepted. His interest in plant physiology did much to advance Cambridge in this study, and his teaching by lectures and text-book was most helpful to students; the "Elements of Botany," although written for the preliminary medical course, was a safe introduction to the study of plant life. As President of the British Association in 1908, he discussed the problems of stimulus and reaction in plants, and by the mnemic hypothesis—the idea that stimuli are not momentary in effect, but leave a trace or record—somewhat expanded, and also supported, his father's views on the origin of species. By his death science loses a considerable personality. His distinction did not clash with his sense of humour, his hatred of insincerity, nor his appreciation of the good work of others.

Annotations.

"Ne quid nimis."

THE SURGEON AS A TECHNICIAN.

UNDER the modest title "De Minimis" Mr. Arthur Edmunds calls attention, in a communication appearing in our present issue, to an aspect of surgery which has of late been seldom made a subject of prominence—namely, the technical details of the surgeon's art. Every surgeon has his own special methods by which in years of practice he has learnt to facilitate his work, but the great surgeons early in the last century took infinite pains to build these methods into a technique having a virtuosity comparable to that of the pianist, by which they triumphed over difficulties and astounded the onlookers. Those were the days when theatre galleries were crowded to see Fergusson amputate a hip in 12 seconds, or to watch the faultless perfection of an operation by Dupuytren or Syme. These men worked when anæsthesia was unknown and when the slightest clumsiness meant the prolongation of the agony of the patient, and it was not for mere spectacular effect that they spent, in acquiring supreme manipulative skill, so much labour as they did. When the enterprising young operators went over to Paris, where bodies were cheap and where perhaps for that very reason the surgeons led the world in technical brilliance, the aim to gain pace and precision was always humane in origin. One English surgeon, not even now an old man, went to Paris to tie the common iliac artery 10 times, so that he might learn to avoid wounding the peritoneum, naturally held in pre-Listerian days to constitute an almost fatal disaster. To-day the whole situation has changed. With the perfection of anæsthetics and of asepsis, the urgent necessity for such manipulative dexterity and speed has gone. The surgeon's work has been made so much easier in one sense—though so much harder when its range is remembered—that he is apt to forget that it really does matter how an operation is done; and authors have chronicled in our pages before now the details of surgical procedures where unimpeachable as the objects have been, the methods have had no reason for commendation. The results in such cases may have been generally good, or unfortunate issues may have not been traceable to faulty technique, for the human body is amazingly tolerant; but none the less the operation that is performed with an accurate knowledge of anatomy and a precise conception of the projected steps must remain the proper ideal. But there are difficulties in obtaining the experience thus necessitated. The old surgery consisted largely of amputations and of operations easily carried out on the cadaver. To-day the teachers cannot get the cadavers for the students, and if they could, they would be of little practical use for the carrying out of instruction in the operations on the viscera, which form now so large a bulk of surgery. It is only on living animals that the student could be taught real technique exactly, and such studies are most strictly prohibited in this country, where even the trained surgeon is not allowed to develop his skill in this way. In America, in some of the medical schools at any rate, regular animal hospitals have been organised, in which the student is taught the technique of his art. He is taught to operate upon anæsthetised animals, and to care for his animal patients. The modern surgeon is assisted by anæsthesia and asepsis, adjuvants of far-ranging power, and every day there are being placed in his hands some new products of mechanical or optical skill; but for the development of personal dexterity the medical curriculum makes little provision. Are the difficulties of filling this gap insuperable? The pessimistic view, that we have seen taken in more than one place, that the modern student, wearied with the burden of an overgrown curriculum, reaches the final examinations unable to outline the simplest amputation, and without ever having been taught how to hold a knife or to tie a knot—this view is exaggerated, but there is no doubt that the importance of technique is no longer sufficiently insisted upon by teachers. Their responsibility here is difficult to discharge, and we may see the employment of elaborate dummies or models. Rightly used these could be of enormous service.

NOTIFIABLE DISEASES THROUGHOUT THE WORLD.

THE second annual report on the prevalence of epidemic diseases prepared by the Service of Epidemiological Intelligence and Public Health Statistics of the Health Section of the Secretariat of the League of Nations[1] reviews the statistics for 1924 of the diseases notifiable in 29 European, 17 African, 20 American, and 16 Asiatic countries, together with Australasia. The tables collected in this volume are prepared from the current records published in the Monthly Epidemiological Reports of the League, and are sent to the National Health Services for verification. The short summaries of the movement of the various epidemic diseases during the year provide a review of the general situation. The incidence of plague has been higher than in any of the five preceding years, mainly on account of its prevalence in Northern India. On the other hand, Egypt, Iraq, and East Africa record fewer cases than in 1923. Cholera was rare outside India and entirely confined to Asia, except for nine cases in European Russia. In India it was more prevalent than in the two previous years. Yellow fever reappeared in Central America and 18 cases were reported from British West Africa. The incidence of typhus was lower in all parts than at any time since the war; it would seem that the great pandemic has now run its course. There was a serious epidemic of relapsing fever in Nigeria, but elsewhere the incidence diminished rapidly. Small-pox markedly increased in North Africa and North America, particularly among the natives. The fatality, however, was very low, only two deaths being reported from Africa. In South America there has been a definite decline of this disease. In Europe the situation has improved, although England and Poland report an increased incidence. Enteric fever remains as in previous years, except for a slight increase in Europe; the steady decline observed between 1894 and 1914 appears to have ceased for the time. Serious epidemics occurred in the Balkans. Malaria still constitutes a serious problem in Russia and the Balkan States. The Commission believes that the rise during recent years is due to climatic conditions favouring the spread of the mosquito; and to mass movements of peoples carrying with them new strains of plasmodia. Reliable information on Malta fever is only available for a few countries; it has been reported as far south as Southern Rhodesia and the Union of South Africa, as well as in the West Indies and United States. The great influenza pandemic of 1918–19 has been followed by recrudescences of varying intensity; the epidemic of 1924 was less severe than that of 1921–22, and was most marked in Western Europe. The incidence of encephalitis lethargica was lower in America and in Europe, with the exception of Great Britain, where it was unusually prevalent. In former years most cases occurred in winter, but in 1924 the majority were encountered during the spring. In spite of the serious epidemic in this country the death-rate was low, about 20 per cent., and abortive attacks were frequent. Japan suffered from an unidentified epidemic of the central nervous system, with a mortality of 55 per cent. A severe epidemic of acute poliomyelitis occurred in Iceland, with a mortality of 37 per cent. A large number of cases were recorded in Sweden and in England and New Zealand. Cerebro-spinal fever is notifiable in almost all parts of the world. A period of high prevalence followed the war, but since then there has been a decline. Several important outbreaks have occurred in the grass lands south of the North African desert belt. There seems to have been a slight but by no means general decline of measles during 1924, but, like scarlet fever, whooping-cough, and diphtheria, the disease is not completely reported, and definite conclusions cannot be drawn from the statistics collected here. The seasonal distribution of measles is seen to vary in different countries, and it tends to cause widespread epidemics periodically. The report is lavishly illustrated with maps and diagrams. The compilers admit that for several reasons it is not absolutely complete, but none the less it is an extremely valuable source of information for the student of epidemiology.

THE ROTUNDA HOSPITAL REPORT.

THE clinical report of the Rotunda Lying-in Hospital for the year 1923–24 appears in the August number of the *Irish Journal of Medicine*. As in previous years the report is full and comprehensive and includes a detailed statement made by the Master, Dr. Gibbon FitzGibbon, who summarises the year's work and discusses the various forms of treatment adopted. This summary should be read by all who are interested in midwifery, as it contains many original observations and gives an excellent idea of the work carried out at this well-known Dublin hospital. Attention is here called to a condition, arising wholly in primiparæ, "and described as persistent primary uterine inertia"; its pathology and the treatment adopted are reviewed, and notes appended of eight illustrative cases. In touching upon his method of inducing labour by a soft rubber tube, Dr. FitzGibbon takes exception to the description given of this method by Dr. T. Watts Eden,[1] who writes: "as much of the tube as possible is then gradually passed through the cervix. The excess should be cut off and the vagina packed to keep the tube in place." Dr. FitzGibbon affirms in the treatment of over 100 cases by this means he has never failed to pass the whole of the tube into the uterus. His object in devising the method was to have nothing passing from the uterine cavity into the vagina and to avoid having even iodoform gauze in the vagina to interfere with free drainage. Contrary to usual practice forceps are advocated in the report for the delivery of the breech, and the author considers them particularly suitable in the usual position of delay, at the perineum, more especially when the legs are extended, and greatly preferable in that position to any attempt to pass the hand up to flex the leg. During the year forceps were applied to the breech on five occasions with most satisfactory results. In discussing "contracted pelvis," it is stated that almost every primiparous patient is given a trial of labour up to rupture of the membranes before deciding on delivery by section. Internal pelvimetry was only done once in the year as dependence was placed far more upon the application of the head to the pelvic brim, as made out under anæsthesia, and by noting the progress of labour than on the actual dimensions of the pelvis. It is interesting to note that pubiotomy was only done in one instance. Cæsarean section, however, was performed on 19 occasions; there was no maternal mortality, but five cases were morbid and two infants died. The classical method was followed with the modification that the abdominal incision was begun below the umbilicus, the uterine incision being correspondingly low, generally encroaching for an inch or more on the lower uterine segment. During the year nine cases of eclampsia occurred; these were treated by the routine method of the hospital, morphia only being given if the patient was restless in labour or when returning to consciousness; the maternal mortality was nil but four infants were born dead. Of the 1703 cases confined within the hospital 102 were morbid according to the B.M.A. standard, giving a percentage morbidity of 5·9. There were ten maternal deaths, and 7·9 per cent. of the infants were either born dead or failed to survive the first week. Included amongst the maternal deaths were three cases of rupture of the uterus, one full-term ectopic which died just after a laparotomy, and four cases of acute sepsis. There was also one case of concealed (and revealed) accidental hæmorrhage, associated with pre-eclamptic symptoms and marked albuminuria. This case was treated on conservative lines. At the necropsy hæmorrhages were found under the peritoneum and broad ligaments and the whole of the uterine wall was infiltrated with extravasated blood. There were well-marked degenerative changes in both the liver and the kidneys. In the extern maternity 2001 patients were attended in their confinements, 210 of these being abortions or miscarriages under the twenty-eighth week. There were 11 maternal deaths, and 3·1 per cent. of the infants were either born dead or failed to survive the first week. Amongst the maternal deaths there was one case of post-partum hæmorrhage, one of rupture of the uterus, and one of placenta prævia. During this year 270 patients were admitted for antenatal investigation and treatment and 407 cases were received into the gynæcological wards. Of the latter 320 were operated upon with a mortality of less than 1 per cent. The last 20 pages of the report are allocated to an excellent set of tables giving a statistical synopsis of the various cases met with. Although this statistical enumeration is not as complete as certain of the tables given in some other maternity hospital reports, the deficiency is more than made good by Dr. FitzGibbon's very full opening summary. He and his colleagues at the Rotunda are to be congratulated on an excellent year's work.

PLEURAL EMPYEMA.

THE threatened advent of an early winter, with its attendant visitation of pulmonary infections, brings the subject of empyema once more to a prominent position amongst the anxieties of our readers. So long as such epidemics persist this dangerous complication will continue to take its toll amongst patients who have successfully withstood the first shock of an attack of pneumonia. Difficulty of diagnosis is the factor which perhaps makes empyema most dangerous, and in this connexion the observations of a physician of long experience are always valuable. Such are to be found in an article recently published by Dr. F. J. O'Donnell,[1] who epitomises the experience of many years in an essay dealing with 20 recent cases of pleural empyema. Concerning the diagnosis the writer lays particular stress on four points: the persistence of marked debility, the early onset of facial pallor, an increase in the pulse-rate, and a demonstrable leucocytosis. Irregular pyrexia is almost invariably present, but Dr. O'Donnell finds this to be less constant than the increased frequency of the pulse, and it is worthy of note that fever occurring only for brief periods daily may far more easily escape observation than a rapid pulse, which can be detected at all hours. As to the physical signs, difficulty is experienced in probably the majority of all cases, for though a large collection of fluid at the base of one lung gives characteristic signs, the presence of a small collection of pus in an abnormal situation is not only confusing because of its position, but is often accompanied by the breath-sounds suggestive of consolidation of the lung. The rule adopted by Dr. O'Donnell is "to percuss the chest with a view to finding any area possessing the characteristic flat note suggestive of underlying fluid, and, if found, to explore that area regardless of the nature of the breath-sounds, if any, present there." "In doubtful cases," wrote Locke, "needle the chest early and often," and it may be said that one of the cardinal characteristics of the sound practitioner is that he does not allow the reluctance of the patient or his friends to deter him from insisting on the use of the exploring syringe in every uncertain case. Amongst the infrequent causes of difficulty in diagnosis are abscess of the lung and liver abscess rising to a high level; the discovery of pus in such conditions is still of great importance though the treatment is not necessarily the same. As to the treatment of pleural empyema, Dr. O'Donnell shares the caution of all experienced physicians and prefers to aspirate during the more acute phases of the disease, reserving resection for a later period. He finds that children withstand operation under local anæsthesia particularly well, and he urges the importance of open-air treatment in all severe cases during the period following drainage.

MEDICAL DEFENCE.

THERE are forms of insurance which hold out such compensations for misfortune as to make disasters almost desirable; there are others, of a negative sort, which offer as their greatest inducement the reflection that things might have been very much worse. Few people feel actual pleasure in paying rates towards the upkeep of the police force which, though it may save them from the worst features of burglary, is unlikely to distribute bonuses to its supporters; and the same reluctance is manifest in paying subscriptions to medical defence societies which are merely protective in function. The Council of the Medical Defence Union, which has just published its annual report,[1] welcomes 1118 recruits to its membership during the past year—the membership is now 12,017—but speaks regretfully of this reluctance of medical practitioners to avail themselves of its services. The Union can, however, find little else to deplore in its present position, for it was never so thriving before. Its amenities have also increased. Following the case of Harnett *v.* Bond and Adam, it has been decided to offer unlimited indemnity to members for any damages sustained in a case undertaken by the Union. The Union is enabled to propose these terms by an arrangement with an insurance company by which any excess charges over 25 per cent. of the Union's annual income are borne by the company. The premium for this indemnity insurance amounted to £3377 last year; but the assets of the Union are now nearly £10,000, and this sum is so large that from January next the Union will only insure for charges in excess of 50 per cent. of the income, and the premium will presumably be smaller. This unlimited protection of members in cases which the Union feels it right to take up is offered in return for the small subscription of £1 per year, although the cost of defence last year was in one case as much as £787. Ninety-seven cases were referred to the solicitors, and ten of these were withdrawn soon after the Union agreed to defend them. Only one case was lost and here the damages were greatly reduced. In seven the Union defended its members before the General Medical Council, and in none of these was a name removed from the Register; but the Union finds a difficulty in that the Council's methods are not in accordance with legal procedure. The Council, however, does not pretend to prosecute under criminal law; it tries to discover whether conduct imputed to a medical man infringes the standard which it is the duty of the Council to maintain for registered doctors. Among other matters to which the report draws attention are the services of the general secretary of the Union in adjusting difficulties between medical men; the danger of granting interviews to dissatisfied patients, who may afterwards misrepresent the conversations; the desirability of putting the cases before the Union before taking steps which it may be unable to authorise; the inadvisability of criticism by one doctor of another; and the unwisdom of settling disputes privately rather than facing publicity. It also mentions the fact that the Lunacy Laws only require the exercise in good faith of reasonable care, in contrast to Common Law, which insists in addition on reasonable skill. In the course of its report the Union discusses its relation to the British Medical Association's scheme of defence, and denies that the existing defence societies

---

[1] Report and Statement of Accounts of Medical Defenc Union, Ltd. 1925.

"have been given every opportunity of entering into coöperation," although there have been suggestions that members of the Association should receive favourable terms from the societies. In his special report the Union's solicitor says: "The practice of the profession of medicine undoubtedly entails considerable risk of litigation, as in no other profession is the personal element so predominant and the expectation and ignorance of the public so profound." At a time when challenge of professional conduct is increasingly frequent personal insurance against such risks is practically indispensable, and a recent case has made it clear that in the opinion of the profession at large an unprotected colleague who suffers at the hands of the public has only himself to blame.

FUNGI.

THE great division of flowerless and chlorophyll-free plants known as fungi represent a somewhat neglected source both of food and drugs, for in this country it has been estimated that there are at least 200 edible forms of fungi, and this is but a small proportion of the total species of these plants, of which there are over 5000 in Great Britain. Certain of the species represent a danger to our existing food-supply; the parasites on wheat and on potato plants have of recent years been the object of study by scientific agriculturists. The chief edible species is the mushroom proper, *Agaricus campestris*, and other fungi which are safe for eating purposes and not likely to be confused with poisonous varieties are the parasol mushroom, the inkcap, the beefsteak fungus, and the hedgehog mushroom. A fungus growing on the elder, *Fungus sambuci*, has been used as a local application in conjunctivitis; the puff-ball has a reputation in country districts for arresting hæmorrhage, and a 25 per cent. tincture is sometimes used as a nervous sedative; preparations from certain members of the species of *Polyporus* in the form of agaric acid and its derivatives are sometimes employed in the belief that they check profuse sweating; but ergot alone represents these plants in the Pharmacopœia. In ancient times the eating of fungi was a common practice. The Romans especially favoured the *boleti*, while Celsus has allusions to the use of certain edible varieties. Throughout Europe and in the East fungi are much more widely used as food than in Great Britain, and with the object of remedying this neglect Mrs. Grieve has produced a little book on "Fungi as Food and in Medicine" (price 1*s.* 6*d.* post free from the author, Whins' Cottage, Chalfont St. Peter, Bucks). She first deals with the methods of discriminating between edible and poisonous fungi, and it seems that certain of the traditional ideas with regard to "mushrooms" and "toadstools" are liable to lead to dangerous results, for it must be admitted that the average city dweller is very much at the mercy of vaguely remembered information, usually culled from the "odds and ends" column of some domestic journal. They do these things better in France, however, where the préfecture de police has established a centre of inspection for mushrooms at the "Halles" of Paris. Not only is every consignment of mushrooms entering this market inspected and passed before being put up for sale, but Parisians returning from an afternoon's excursion in the country may have their gatherings of fungi classified by the inspector free of charge. The British mushroom gatherer must acquire for himself a good working knowledge of the appearance of the edible varieties to be really safe, but generally speaking, fungi with evil smells or which turn a deep blue or greenish on being cut or bruised, or with a bitter taste, or which exude a milky juice should be avoided, and it is also important that fungi should be cooked and eaten while fresh. Mrs. Grieve goes on to describe the botanical features of the principal fungi, and follows her description of the plants with either a list of tasty recipes or poisonous symptoms according to their edible properties. The popular names of many of the fungi are in themselves attractive; "rough-legged boletus," "Jew's ear," "tinder bracket," "horn of plenty," are some examples, while among the recipes "procera pie" and "deliciosus pie" (from the "milky orange mushroom") look as if they deserved greater popularity. Truffles are more used in France and Italy than in this country mainly because the French truffle has a superior flavour to that of the English variety, and those sold over here being mostly imported and far from fresh give only a faint idea of the true truffle flavour. The fungus season begins at the end of April with the appearance of St. George's mushroom, and throughout the year until the end of October various varieties may be gathered. A most useful addition to our food resources in this country seems to be almost entirely neglected, and medicinal properties attributed by tradition to certain species of fungi may possibly represent an untapped source of therapeutic virtue.

PNEUMOCOCCUS IMMUNITY.

RESEARCH on pneumonia, which has been so well carried out by American workers during the last few years, has recently been advanced a further stage by the publication of a monograph on pneumococcus immunity[1] by R. L. Cecil, G. I. Steffen, H. S. Baldwin, and Dorothy R. Rhoades. The first part of the report consists of experiments by Dr. Cecil and Dr. Steffen with a view to producing active immunisation of monkeys against pneumococcal pneumonia. Intratracheal injections of monkeys with three doses of pneumococcus vaccine rendered the animals immune, in the majority of cases, to subsequent injection with pneumococci of homologous type, but administration of the vaccine by means of a spray did not produce so satisfactory a resistance. Little or no protective substance against the pneumococcus could be detected in the blood serum of the animals vaccinated by intratracheal injection, the immunity apparently being rather cellular than humoral. Experiments were also made by the same authors to demonstrate the effect of treatment of experimental pneumonia in monkeys with pneumococcus antibody solution prepared by the method of Huntoon. This antibody solution proved to be effective when used as a curative agent intravenously in monkeys injected with Type I. pneumococcus, less so with Type II., and ineffective with Type III., and with the one strain of Group IV. tested. Pneumococcus antibody solution was also effective in the treatment of Type I. pneumonia when injected subcutaneously. The report further contains a record of some investigations made by Dr. Rhoades on the fate of pneumococcus protective bodies when injected into normal animals and man. For this purpose two methods of obtaining the protective substance were employed—viz., Huntoon's and Felton's—both of which consist in separating out the globulin fraction from antipneumococcus serum. When solutions of this antibody are injected intravenously into the normal rabbit or man, protective substances against Type I. pneumococcus are demonstrable in the peripheral blood immediately after the injection and for a short period following; when animals were injected intraperitoneally, similar results were obtained, but when the subcutaneous route was used the appearance of protective substance was more variable. No protective substances could be elicited by the administration of these antibody solutions by trachea, mouth, or rectum. Finally, Dr. Baldwin and Dr. Rhoades report on bacteriæmia in pneumonia and its relation to the crisis. One hundred and seven cases were investigated from the wards of Bellevue Hospital, New York. The tabulated results show that with all types of pneumococcus the death-rate is much higher in cases with positive blood cultures than in cases with sterile blood. They find that pneumococci and protective antibodies rarely appear simultaneously in peripheral blood. The same workers record work done on the use of ethylhydrocuprein in lobar pneumonia. They write guardedly of their results, but consider that there is some evidence of bactericidal effect.

TUBERCULOSIS IN THE ITALIAN NAVY.

Surgeon-General Filippo Rho, formerly Medical Director-General of the Italian Navy, and a leading authority on naval hygiene, discusses, in a paper reproduced in the *Military Surgeon* for July, the question of tuberculosis in the Italian Navy, in which service there are always more cases than in the Italian Army, the experience here being also that of France. In Surgeon-General Rho's view the chief factors accounting for the discrepancy are infection and healthy carriers, and neither predisposition nor the often-quoted hard work and exposure; while he is confirmed in this, his long-held opinion, by the experiences of the war, which did not increase the incidence of tubercle among the soldiers. For seven years he was medical officer to the Naval Academy at Leghorn and in that time saw only two cases. But in 1919 a case appeared, followed during the same year by six others, always in the same class and dormitory, though each was promptly isolated as it appeared. There must, he thinks, have been a healthy carrier, and we may suggest that an attendant was perhaps the peccant subject. Many appear to hold that the tuberculous are more likely to recover from consumption on board a ship than on shore, but this is a mistake, at any rate as regards men-of-war, as the Italian figures show. The morbidity from tubercle in 1893–97 in the Italian Army was 1·9, and in the Navy 2·0 per mille—surely called "percentages" in error. But the liability is not uniform for all men in the naval service. The liability of sailors, in 1893–97, was 1·6; that of writers, firemen, and attendants on the sick was between 3·2 and 3·5, or about twice as much. Small cubic space increases the incidence of tuberculosis, the narrow environment being more favourable for the growth of the tubercle bacillus. Surgeon-General Rho hopes much from the new copper compounds, double cyanides, which have shown good results in Japan and Italy, and not only against tubercle, but against leprosy, in the hands of Matta and Devoto, at Cagliari. His paper is worth close consideration.

CHRONIC PEPTIC ULCER IN CHILDREN.

IN a recent thesis for the degree of Master of Science in Surgery at the University of Minnesota, Dr. Oscar S. Proctor[1] discusses the subject of chronic peptic ulcer in children with a review of the literature and a record of three hitherto unpublished cases observed at the Mayo Clinic. Study of the literature showed that there were only 10 undoubted cases and two which were questionable. The patients included in this series were aged 14 years and under. The cause of chronic peptic ulcer in children is probably the same as in the adult. Two-thirds of the recorded cases were in females. The situation of nearly all the gastric ulcers was on the lesser curvature at or near the pylorus as in the adult. Approximately one-third of the ulcers were associated with definite stenosis of the pylorus. There was no indication that any of the gastric ulcers became malignant during childhood. The onset may be sudden with hæmorrhage or perforation, but this is very exceptional, and there is usually a history of gastric disturbance extending over months or years. The symptoms may be mild and attract little attention, consisting in pallor, anorexia, loss of weight, and vague abdominal pain, but as a rule they are very definite and sometimes severe. Epigastric distress or pain of varying degree is present in practically all cases, lasting from a very short period to several hours. Nausea and vomiting are present in most cases. Constipation is the rule and is often obstinate. Retarded development is often apparent and may sometimes amount to complete cessation of growth. The figures are, of course, too small to draw exact deductions, but bleeding was present to some extent in about 40 per cent. of the cases. Perforation occurred in about 25 per cent. General peritonitis in such cases was almost always present, and the mortality has been about 50 per cent. As regards diagnosis, chronic or recurrent dyspepsia in a child should suggest the possibility of peptic ulcer, especially if the growth is retarded or if the child is under weight or pale. Hyperchlorhydria is usually absent; when present it may be helpful in diagnosis. Blood may be found in the gastric contents or in the stools, especially on repeated examination. X rays are of great assistance in diagnosis, as was exemplified in two of the writer's cases. Unless there are definite contra-indications such as marked pyloric stenosis, repeated hæmorrhage, or perforation, medical treatment should always have a thorough trial, and if it fails the simplest operations are best, such as pyloroplasty or gastro-enterostomy.

THE LATE DR. LOUIS STARR.

Dr. Louis Starr, who died recently at Dinard at the age of 76, was one of the best known authorities in the United States upon the diseases of children. Born in Philadelphia, he graduated at his native University in 1871, and in the famous American city he conducted for many years one of the largest practices in the world in pediatrics, writing also widely on his specialty as well as editing the works of others. Since his retirement from practice Dr. Starr has been living at Dinard, and some of our readers may have seen his delightful etchings illustrating scenes in the immediate neighbourhood, especially in Dinan. An old friend writes: "Dr. Louis Starr's health had for some years been precarious, and the loss in the war of his only son remained an abiding source of grief to him, although those who visited him at his beautiful villa will remember that no word of complaint either of his grief or of his physical pain ever passed his lips." We tender our sympathies to his widow and devoted companion.

WE regret to record the death of Dr. James William Russell, joint professor of medicine at Birmingham University, on Sept. 20th, after a short illness, in his sixty-third year.

THE King has granted a charter to the Medico-Psychological Association of Great Britain and Ireland, which will henceforth be entitled to the prefix "Royal."

THE annual meeting of the Fellows and Members of the Royal College of Surgeons of England, which takes place on Nov. 19th, will be an occasion of interest, as the Council of the College, we are informed, has decided to lay before the meeting the exact terms of the petition for a proposed new charter, an interesting point in which is the suggested admission of women Fellows on the same status as men Fellows.

THE University Court of St. Andrews University has appointed David Rutherford Dow, M.D., D.P.H. St. And., of Crail, Fife, to the Chair of Anatomy in University College, Dundee, rendered vacant by the retirement of Principal J. Y. Mackay. Since 1913 Prof. Dow has been lecturer in regional anatomy at the United College, St. Andrews, and assistant successively to Profs. J. Musgrove and D. Waterston. He has published several papers on research work in anatomy.

INFANT CARE.—A series of elementary lectures on infant care for creche nurses and probationers will be given by Dr. Stella Churchill at Carnegie House, 117, Piccadilly, W. 1, under the auspices of the National Association for the Prevention of Infant Mortality and the National Society of Day Nurseries, on Thursday evenings from Oct. 15th to Dec. 17th. Full particulars may be obtained from the secretaries of either of the above societies at Carnegie House.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXL.—THE SURGICAL TREATMENT OF EXOPHTHALMIC GOITRE.

PART II.*—THE OPERATION AND ITS DANGERS.

THE surgeon who is practised in operating upon patients with Graves's disease can judge from his experience how much should be done at one operation in each individual case. The same surgeon will, in one case, simply ligature and divide an artery; in another he will remove one lobe and the isthmus; in a third he will remove one lobe, the isthmus, and from half to two-thirds of the second lobe. A surgeon who is not practised will begin by ligaturing one artery and dividing it. He will do this for several reasons. It tests the patient's reaction to operation by something smaller than the extirpation of a lobe, and the reaction is, to some extent, an unknown quantity in Graves's disease. It will also temporarily improve the patient's condition, so that a bigger operation can be undertaken later with more safety. An operator unpractised in these cases may kill a patient by mere length of time taken, together with the unavoidable handling and the hæmorrhage, if he attempts too much at the first operation. But no one should operate upon a case of Graves's disease at all unless he is prepared to do ultimately all that is necessary to cure the patient. To remove one lobe is comparatively easy. To slice through the second lobe may present many difficulties; but to do the former only and to leave the patient at that stage is to bring into disrepute the operation for the cure of exophthalmic goitre.[7]

Steps of the Operation.

The steps of the operation may be briefly recapitulated.[8] A "collar" incision is made following Kocher's plan. This incision is always adhered to no matter how large the goitre. The flaps, including the platysma, can be dissected up and down sufficiently to give good access, whether the lobe is approached subsequently through the mid-line, or by an oblique division of fascia in front of the sterno-mastoid. My own plan after the reflection of the flaps is to make a stab through the lower flap for subsequent insertion of a drainage-tube. The infrahyoid muscles and fascia are separated in the mid-line; if this is carried out from the larynx to the sternum the muscles can be retracted sufficiently for the enucleation of almost any lobe without lateral division of the muscles. Nevertheless, if the patient is very ill, or the lobe is big, division of these muscles will permit of enucleation with less manipulation. The superior vessels are clamped in two places and divided; these vessels should never be ligatured in continuity, for the upper pole is drawn down so far that any simple ligature may easily slip. Enucleation is carried out by peeling back the fascia from the lateral aspect of the lobe with plain forceps, while the lobe is gently rotated on its longitudinal axis towards the other side. It is wise to leave a thin shaving of thyroid overlying the region of the recurrent laryngeal nerve so that this may be protected. I believe that more damage is done by stretching the nerve in rough manipulation, or by infiltration following the damage to the surrounding structures, than by actual cutting it across or catching it in forceps. The latter may occur unless the surgeon keeps very accurately to the right plane, and unless hæmostasis is meticulously carried out as the operation progresses. The isthmus should be removed with the first lobe unless the patient is too ill, as this facilitates the second operation. Otherwise the isthmus becomes buried in scar tissue, and its subsequent removal is accompanied by much bleeding and consequent blurring of the field. On the other hand, if it is left at the first operation, and not completely removed at the second, so much of the gland remains that the patient does not receive the maximum benefit from the operation.

The second lobe will probably be dealt with some months later. The original incision is opened, the flaps are reflected as before, but the vertical incision through the deep fascia and infrahyoid muscles will be made laterally, and not in the mid-line, in order to approach the lobe at a place free from the scar tissue of the first operation. The whole field must be clearly defined before the lobe is cut into. Enucleation will be commenced at the lower pole for several reasons; it is the larger pole and it is easily rotated forward on its attachment to the trachea by the scar tissue of the previous operation. Therefore its resection can be commenced by cutting into it from behind, and a large part of the lobe removed while the upper pole with its blood-supply is undisturbed. The procedure is as follows: a row of pressure forceps are placed on the capsule of the lobe, the lower ones being behind the lower pole, the remainder in a line approaching the lateral surface in front of the region of the recurrent laryngeal nerve and gradually coming forward on to the anterior surface as the upper pole is approached. These forceps grip vessels and arteries in the capsule and act as guy-ropes, so that the bleeding from the cut surface is under control until it is dealt with. Hæmostasis must be absolutely complete, and I believe that fine silk (or thread) is the only safe ligature for this reason—catgut loosens too readily through movements of the larynx and trachea in swallowing or coughing, and late hæmorrhage is a very serious matter.

Drainage at both operations is provided for by a split drainage-tube passed through the stab down to the bed of the thyroid. The infrahyoid muscles and fascia are brought together above this, the flaps of the collar incision are united by buried catgut sutures, which pick up the platysma, and the skin is closed by interrupted horse-hair sutures. These sutures and tube are removed in 48 hours, the flaps being held in position by the deep catgut sutures.

Dangers.

There are dangers peculiar to operation on patients suffering from this disease, and these must be given due consideration. In the first place, the selection of the case is important. Patients are not operated upon unless they are ill enough to warrant it; on the other hand, some are too ill. To operate upon a patient with increasing pulse-rate, high basal metabolic rate, mental agitation and emaciation is to invite disaster, and yet patients and friends, when they realise that ground is being lost, will often plead for operation.

Anæsthesia has some dangers. The heart is already suffering from intoxication, so that its margin of safety is a narrow one. Chloroform is absolutely contra-indicated. A skilled anæsthetist may give it with comparative safety, but many lives have undoubtedly been lost through it. If the surgeon has the complete confidence of the patient, local anæsthesia, preceded by omnopon ⅓ gr. and scopolamine 1/150 gr., is ideal; but to an anxious patient general anæsthesia should be given. I prefer ether administered by an endotracheal tube, but the method may be left to a capable anæsthetist who appreciates the conditions, and can manage his apparatus so that it does not hamper the surgeon. Ether should be preceded by a hypodermic injection of atropine to lessen secretion. Waiting in the anæsthetic room should be avoided.

While there should be no undue haste, a prolonged operation and the hæmorrhage associated with it definitely increases the risk. As Sir Berkeley Moynihan has so aptly pointed out in reference to gastric surgery, speed should be attained not through hurry, but through the precision which comes with practice.

---

* Part I. appeared in this series in THE LANCET last week.

[7] Dunhill, T. P.: THE LANCET, 1917, ii., 883.

[8] Same author: Brit. Jour. Surg., 1919, vii., No. 26, p. 195.

Two dangers associated with technique are injury to one or both recurrent laryngeal nerves, and to the parathyroid glands. The former of these is much more common than is usually recognised. If one alone is injured functional recovery of voice is good. If there is delay in this it has been demonstrated that re-educational methods rapidly improve the patients' comfort (Cortlandt MacMahon). If both nerves are injured the last state of the patient is worse than the first.

A danger not sufficiently recognised is that of slow hæmorrhage occurring beneath the deep fascia and the infrahyoid muscles after the patient has returned to bed. This may happen either through incomplete hæmostasis during the operation or afterwards through movements of the larynx and trachea in coughing or vomiting, which may dislodge one of the numerous ligatures. The danger is not from loss of blood, but from increasing pressure on the trachea as the blood collects in the cavity between the vertebræ and deep fascia. The small drainage-tube soon becomes blocked with clot and fails to relieve the pressure.

Results of Operation.

The risks may appear to be so many that the practitioner may wonder if operation should be entertained. If the right time is chosen, due precautions observed, and the operation performed with precision, the results are striking, and the relief to the patient very great. There are those who believe that the signs of exophthalmic goitre are only the manifestation of general endocrine disturbance, but the result of the operation is so obvious that we are compelled to believe that whatever the primary cause of the disease may be the immediate seat of the evils which make the patient's life so unhappy is the disturbed thyroid gland. After operation the pulse-rate drops quickly, the skin becomes cool, the mental agitation subsides, there is always some recession of the eyeballs, and the feeling of strain at the back of the eyes disappears If amenorrhœa has been present the periods become regular.

It is known that in the later stages of thyrotoxic disease, when cardiac compensation has been lost, auricular fibrillation not infrequently results. It has been shown recently that after a sufficient removal of pathological thyroid gland in this condition the auricular fibrillation disappears spontaneously and the heart rhythm becomes normal in many cases. In those patients in whom the pulse does *not* return to normal rhythm after partial thyroidectomy alone, it can be rendered normal by the administration of quinidine, and will, in most instances remain so; whereas without operation normal rhythm cannot be maintained by the use of quinidine alone.[9] [10]

A CONFERENCE ON LIBRARIES.—A conference is being held over the present week-end (Sept. 25th–28th) at Balliol College, Oxford, under the auspices of the Association of Special Libraries and Information Bureaux. The Association exists to facilitate the use and coördination of all sources of information for scientific, technical, commercial, and public purposes. Sessions will be devoted to the present position of the special library movement; to informational work in politics, business, science, engineering, transport, medicine, and patents; and to public and university libraries, &c. A large mass of printed information lies idle through lack of coördination, and this fact naturally makes many and varied bodies interested in the conference. A number of Government departments will be represented, and also learned societies, research associations, the political parties, and many other organisations. The Minister of Labour (Sir A. Steel-Maitland) is opening the proceedings, and a long list of speakers includes Sir Horace Plunkett, Prof. Gilbert Murray, Prof. A. F. Pollard, and Dr. Chalmers Mitchell. The address of the Association is 38, Bloomsbury-square, London, W.C. 1.

Special Articles.

AMERICAN HOSPITALS.

BY LIONEL G. PEARSON.

(*Adams, Holden & Pearson, Architects, Knightsbridge.*)

AMERICA is a good country to visit—people are extremely friendly, hospitable, and ready to show everything to the visitor from across the Atlantic, and anyone who wishes to study their buildings is sure of a very pleasant experience.

Of course the ground to be covered is immense, and the amount of hospital building so great that it is somewhat difficult to make a choice of what to see, especially as authorities have a way of differing as to the relative merits of various cities and buildings. New York City makes the best starting-point without any doubt, for though the Americans deny that it is a typically American city, the fact remains that the best examples of recent architecture are to be found there, whether it is a question of banks, railway depôts, hotels, apartment houses, or hospitals. The pace at which New York (or other cities to a lesser degree) is being rebuilt is astonishing, and it is this extraordinary building activity, the result of commercial prosperity, which makes America at the present moment the most exciting country in the world architecturally. After New York the big new cities of the Middle West probably contain the most interesting examples of recent buildings. California, which has developed on rather different lines from the rest of the country, was too far off to visit in the time at my disposal.

One of the first things that strikes a visitor from England is the importance of mechanical means of heating and ventilation in America. In summer the electric fans and cooled air, in winter the use of radiator and heated air, have had the result that even in hospitals the open window which we consider the first consideration of health is not quite so much the matter of course over there.

The Pavilion Type Obsolete in America.

In any case the pavilion type of hospital with the cross-ventilated ward of between 20 and 30 beds no longer meets present-day requirements in America. Even where the large wards exist, the tendency now is to divide these with glazed screens so that cases can be classified and segregated. The Vanderbilt University Hospital at Nashville, Tennessee, is typical of present-day requirements. (Fig. 1.) Here a ward unit of 30 beds is made up as follows: open ward of 16 beds divided into four cubicles of four beds each, and the remaining 14 beds into four-bed, two-bed, and single bedrooms. Dr. Winford Smith, of the Johns Hopkins Medical School, Baltimore, Maryland, who acted as consultant for this scheme, advocates the use of wards 40 ft. wide, so that the patients' beds may be at right angles to the window in order to avoid light in the patients' eyes, and this width also is useful in planning the lower floors for other departments.

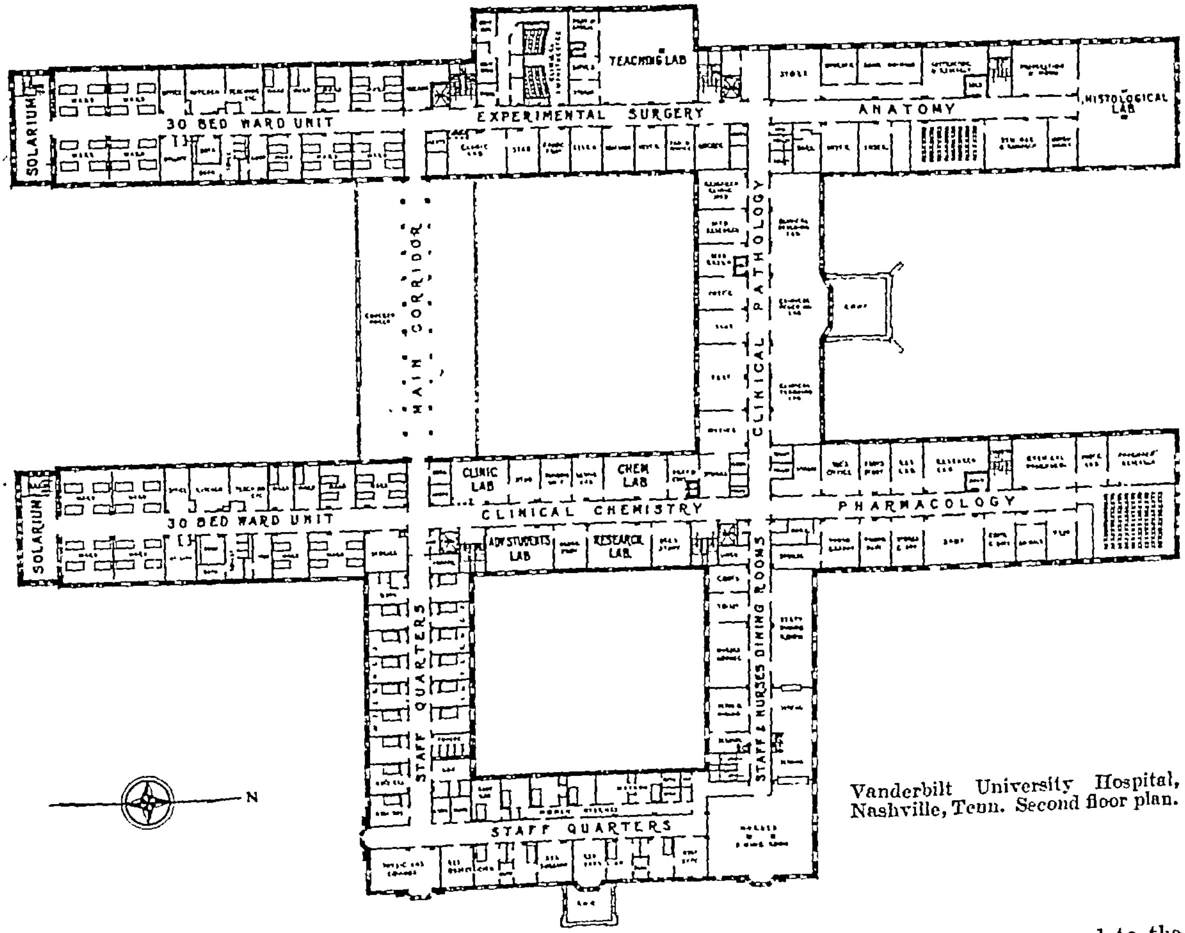
Provision of Private Rooms.

There are, of course, hospitals such as the Henry Ford Hospital, Detroit, Michigan (400 beds) (Fig. 2), and the Fifth Avenue Hospital, New York City (420 beds) (Fig. 3)—the latter being probably the best planned and equipped city hospital in the world at the present time—which consist entirely of private rooms, but these are still the exceptions, and it is more usual for a hospital to erect a pavilion of private rooms for paying patients. A very good example of this is to be seen at Mount Sinai Hospital, New York City, which was erected under Dr. Goldwater's direction for 131 patients, and embodies most of the best ideas of the day in this class of building. The low pavilion type of ward building is also unsuited to the city site where the majority of hospitals are of necessity located.

Vertical Height in Relation to Concentration.

The new Columbia Presbyterian Hospital in New York City is to be 15 storeys. The Fifth Avenue Hospital, N.Y.C., is 10 storeys; St. Luke's Hospital, Chicago, 19 storeys; and even on a comparatively open site it is not uncommon to have a 6-storey building. This is not only a question of the value of the site, but also very much a question of service. The American believes very strongly in concentration, and vertical buildings are much more suitable to the elevators and shutes and all the mechanical equipment of the present day than the spread-out horizontal type of building where the staff must walk long distances, and the plumbing, heating, refrigerating, and drainage services must be less concentrated and efficient.

FIG. 1.



Vanderbilt University Hospital, Nashville, Tenn. Second floor plan.

The elevator plays an important part in modern American life, and in hospitals, as in other buildings, the staircase is relegated to an inferior position and used mainly for fire-escape and floor-to-floor services. The elevators must, of course, be near the main entrance hall, which is generally made as attractive as possible architecturally, and follows the lines of the hotel as far as possible. This idea is also noticeable in the waiting-room, which is invariably comfortably furnished in the style of a hotel lounge, and the private room adjoining the superintendent's office, where financial matters may be discussed without disturbance. But perhaps the most characteristically American side of the administration is the record system to which a great deal of attention is directed. A large room near the entrance is usually assigned to this department, and in the out-patients' department of the Boston City Hospital there is a Lamson system of carriers for conveying the records to various departments, such as X ray, skin, &c., on different floors of the building.

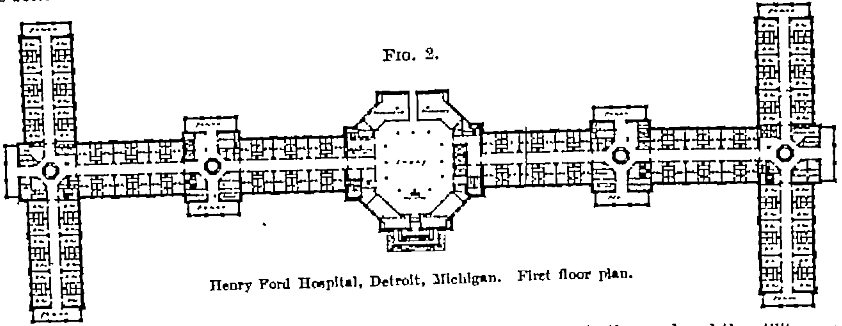
The Food Service.

The food service is usually very efficient, and as great attention is paid to diet a portion of the main kitchen is frequently separated for this purpose under a special dietitian. In the case of the larger hospitals the food is conveyed from the kitchen (which is as near as possible to the elevators) to the diet kitchens on the ward floors in electrically-heated trucks, but in the smaller hospitals where the food trays are set up in the main kitchen, these are conveyed to the diet kitchens in dumb-waiters (small service lifts). The main kitchen is too often in the basement, and it is questionable whether this is good for the health of the staff, however perfect the mechanical ventilation may be. The kitchen at the Peter Bent Brigham Hospital, Boston, Mass., which is on the top floor, is a pleasant contrast in this respect. In this section it may be noted that the food is stored in refrigerators, and the same applies to kitchens on the ward floors. The nurses and staff dining-rooms are frequently arranged as a cafétería (this is a popular form of self-service restaurant throughout the States), but it is doubtful whether the tired nurse altogether appreciates this system in spite of many advantages.

Labour-saving Arrangements.

Laundry arrangements are, as one would expect, very up to date and efficient, and the system of dealing with linen and surgical dressings is thoroughly considered in the planning of the building. The linen shute is a feature of American hospitals, and consists of a circular glass-lined tube 2 ft. in diameter, with a port-hole opening on every floor and a flushing ring at the top with drain connexion at the bottom. This is a labour-saving device much in use in hotels and private residences, but it has the objection that it may convey foul air from the disinfecting room at the bottom of the shute to the various floors. However, there is no doubt that as far as labour-saving devices are concerned, America leads the way, though one feels that in a hospital the health of the patient is even more important than the question of service economy. The system of "signal lights," by which patients summon the nurse at night and the doctor is "warned for duty," is another device without any drawbacks.

FIG. 2.

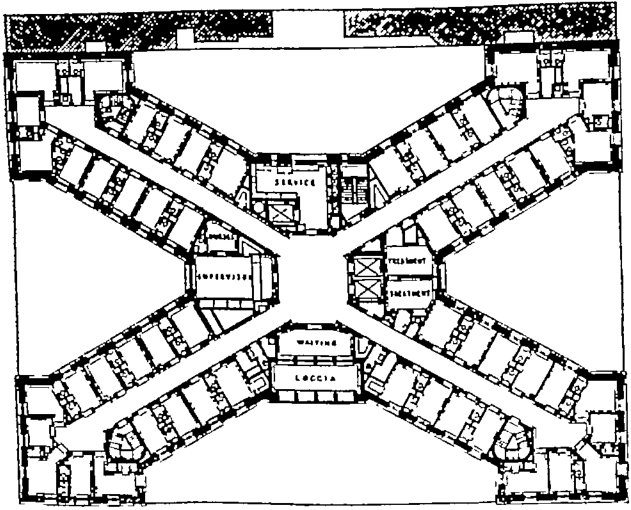


Henry Ford Hospital, Detroit, Michigan. First floor plan.

Sanitary Arrangements.

The sanitary arrangements are fundamentally different from those in this country. The chief cause of difference is that the soil and waste pipes, partly on account of the severe winters, are placed on the inside walls of all buildings, and it is not considered objectionable to open a toilet room direct off a bedroom and to rely on mechanical means of ventilation rather than a window direct to the open. This attitude to plumbing has profoundly influenced the planning of hospitals, where the sanitary tower with cross-ventilated lobby is almost unknown. In the case of the ordinary ward, the toilet and bathrooms open off the corridor leading to the ward, and the utility room (which contains the sinks, bed-pan steriliser, &c.) is also placed in a similar position. In the case of the private room, in some cases there is a separate toilet and bathroom to each room; in others the bathrooms are shared between two or more, but there is usually a lavatory basin (termed "running water") in every room and the w.c. is provided with a jet or special swivel tap, so that the bed-pan can be emptied without any travelling. As regards baths, Dr. Daugherty, of the Brooklyn Lewin Hospital, found these were unnecessary in his paying patients' block, as he only admitted acute cases.

FIG. 3.



Fifth Avenue Hospital, New York City. Typical floor plan.

Another fundamental difference between English and American plumbing is that in the latter case the pipes are not usually exposed on the surface of the wall or ceiling, but are "buried," in the case of the wall in a wide cavity, and in the case of the ceilings covered by a sub-ceiling. This results in a very smart appearance, especially in the case of operating theatres, and is undoubtedly excellent from the point of view of cleaning. But several medical superintendents spoke rather sadly of the results when a pipe burst, when the ceiling has to be "torn down," or the wall opened up at great expense, although this can be obviated to some extent by inspection openings at junctions, &c.

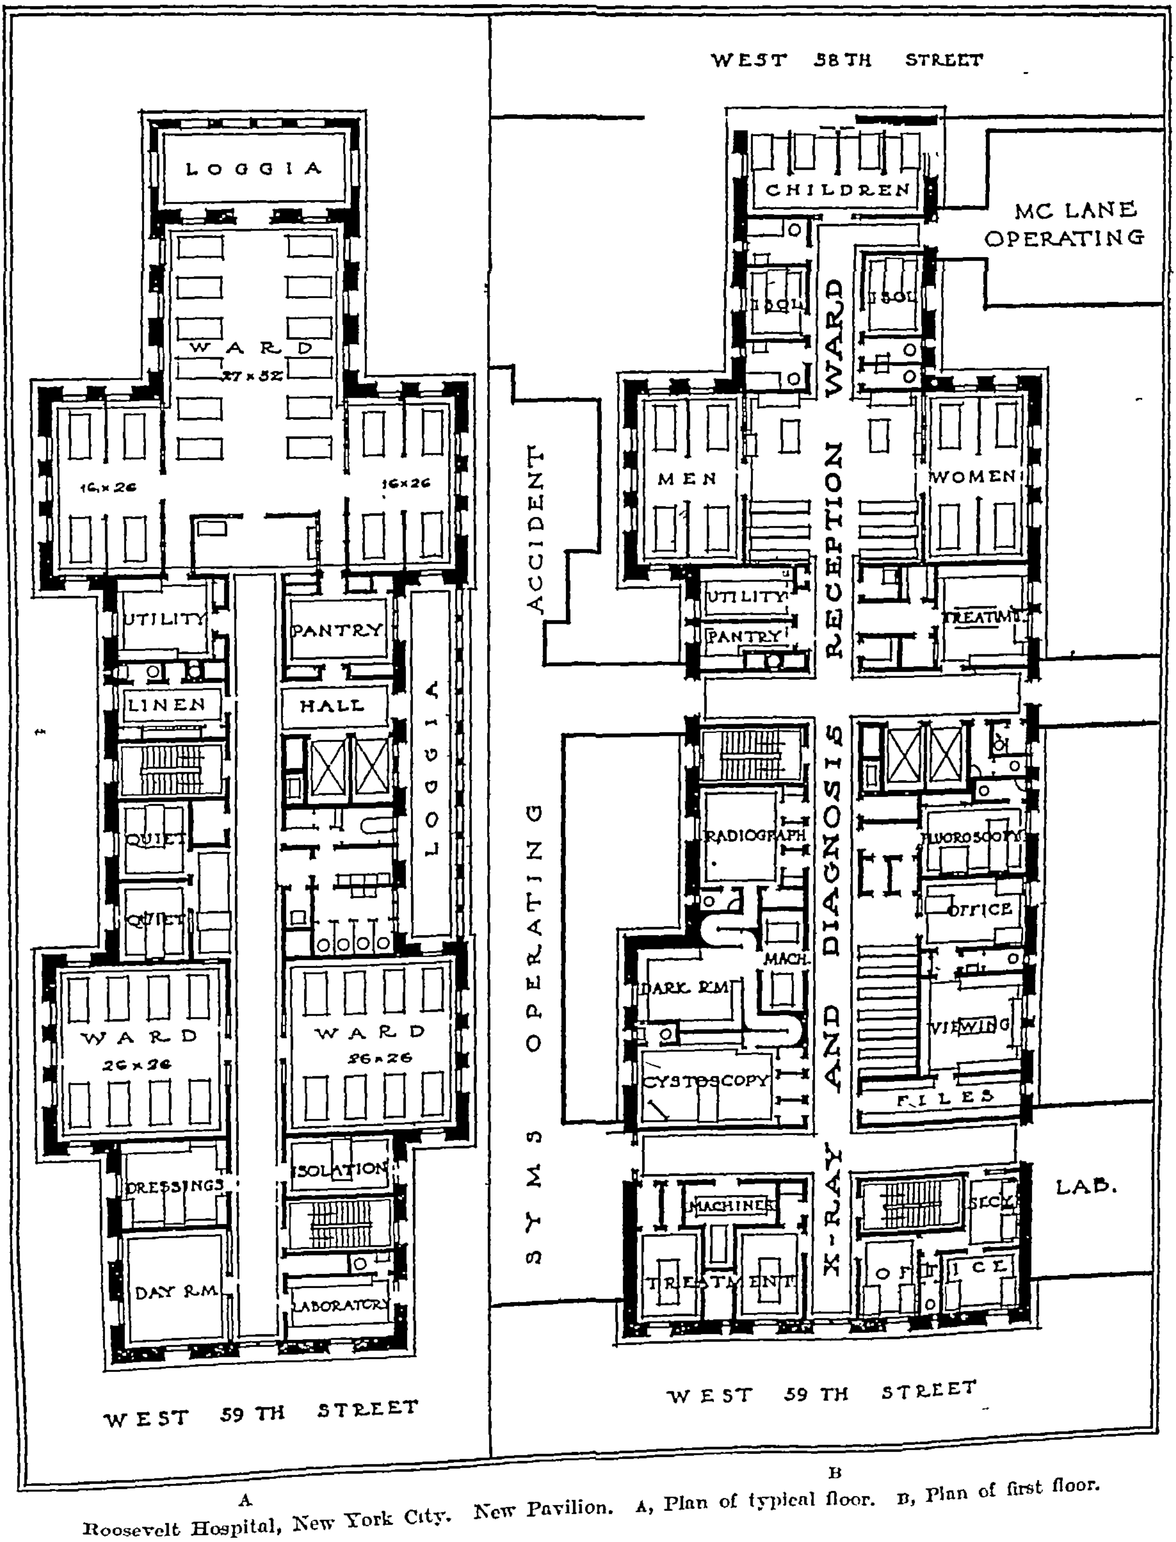
The nurses' station in the case of large wards overlooks the wards; in the case of private rooms is placed centrally either in the corridor or in a room divided from the corridor by a glazed screen. The provision of scrubbing rooms, flower rooms with sinks, a laboratory for routine work, and a comfortable waiting-room, is usual on every floor.

Operating Theatre.

The operating theatre suites are very much on the same lines as the English model. There is usually a sterilising room and a scrub-up room (with borrowed light) between two operating theatres, and the instrument cases are neatly arranged sunk into the wall flush. The floors and walls (up to door height) are now invariably covered with light grey or light green tiles, as this is considered more restful in the eyes of the operator; in one instance—at the Crile Hospital, Cleveland, Ohio—the floors and walls of the operating theatres are covered with rubber tiling, but this is not considered so sanitary as the tiling or terrazzo. The window is usually double up to transom level and the air between the two windows is warmed, so that there is no draught on to operating table.

There are various types of electric light in use, such as "Scanlan-Morris Noshadowite" (eight con-

FIG. 4.



Roosevelt Hospital, New York City. New Pavilion. A, Plan of typical floor. B, Plan of first floor.

verging lights in a ring), "Frink Operating Table Reflector" (with automatic ventilation to counteract heat generated), and the "Operay-multibeam" (adjustable light with lenses and mirrors), but the "Portable Scialitique" seems the favourite at the moment. The American surgeon appears to have little use for natural light, and operations are usually performed by artificial light. Dr. John Clark, of Philadelphia, has arranged an operating theatre at the University Hospital with a falling shutter of the shop-front type, behind which the patient is prepared, while the operator can use the front of the shutter for slides and diagrams facing the students' seats—at the time of operation the shutter is, of course, raised.

X Ray Departments.

The increasing importance of X ray work is nowhere more fully recognised than in America, where the use of X ray for diagnosis has reached such a point that in one important hospital over 75 per cent. of the patients are now X rayed. The result is that there are now many well-planned and splendidly equipped X ray departments, and one of the best of these is to be found at the Roosevelt Hospital, New York City (Fig. 4), where the architects (Messrs. York and Sawyer, who also designed the Fifth Avenue Hospital and many other well-known public buildings) worked out a plan in conjunction with Dr. Steiner. The department is situated on the ground floor near the operating block, and conveniently placed for the out-patients, and consists of a radiographic room, dark room with special light-excluding pass-boxes of a revolving type, cystoscopic room, fluoroscopic room, viewing room, with an excellent set of viewing boxes made of enamelled steel and filled with Cooper-Hewitt lights, and a room for files. The treatment rooms are in a corner of the building cut off by corridors from the rest of the department, and special precautions are taken against rays, as the whole of the walls and ceilings are treble-lined with lead, wire-mesh, and finally glazed tiles, and the floor is lead and cork.

There is another very fine X ray department at the Boston City Hospital in the New Thorndike Memorial Building. This department is on two floors—on the ground floor are waiting-rooms, radiographic rooms, viewing room, and records; in the basement are the treatment rooms (with machines enclosed in a room 6 feet wide between two treatment rooms in every case), an exceptionally fine dark room with smaller rooms for wet plates, plate loading, &c. Special attention has been paid to the ventilation, an important point, unfortunately too often overlooked with resultant damage to the health of the assistants. There is a lecture hall at the end of the corridor two floors in height for the use of the department, so that altogether this is in many ways a model of what an X ray department should be. The colour of the walls found to be most satisfactory by the X ray men is orange or buff, and several departments have plastered walls coloured to these tints, and the floors are usually tiled like an operating theatre or covered with battleship linoleum with a border and skirting of terrazzo.

Open-air Arrangements.

The exposure of patients to fresh air and the sun's rays has affected the design of American hospitals considerably. The covered-in balcony at the south end of the ward block is still a favourite arrangement, as it is in England, but there is a development of this idea which is in many ways preferable, by the provision of a loggia in a central position, as in the Fifth Avenue Hospital, where it does not shut off any light or air from the patients' rooms, or more frequently by the use of a sun-room on the top of the hospital, furnished with easy chairs and with French windows opening on to a flat roof. In the case of private pavilions, a separate small balcony is quite often allowed to each room so that the patient's bed can be partly in the open air.

American and English Hospitals Compared.

In conclusion the question might be asked, "How do American hospitals compare with English?" and though differences of climate and custom account for many things that seem strange to us, the general impression remains that the ideals aimed at are the same in the two countries (the English hospital tradition must have had considerable influence over there), but that in some ways they have gone ahead of us. The love of system and business efficiency which is characteristic of the modern American business man (not necessarily of the Babbit type) has been applied to hospital planning with good results. The course of the patient from the time he enters the building to the time he leaves it (dead or alive) is traced just as Henry Ford traces his car production, and the same may be said of the food service, &c., and a considerable saving in running costs is effected in this way though, of course, this usually means increased capital outlay.

As to the tendency to rely more and more on mechanical contrivances there is certainly a reverse side to this, as Americans themselves realise in industry, for "the human touch," which is specially necessary in the treatment of disease, may suffer as a result. Perhaps it is lucky for us in some ways that our comparative lack of money makes us spend less on these things. Also we are more sceptical about new inventions, and not so eager to scrap old methods and adapt new ideas as the Americans. They take the risk as one of them once said to me, "of making great big mistakes sometimes."

The question of the paying patient (whose advent has resulted in the private room and individual sanitation) is partly an economical one, and we have not such a large class of comparatively well-to-do middle-class patients to draw on in this country. But in England, too, the future will see considerable developments in this direction, and in working out our own problems we can undoubtedly learn much from the study of the fine work carried out by the hospital committees, medical men, and architects in America.

INDUSTRIAL HYGIENE.

AMSTERDAM CONGRESS, SEPT. 6TH–13TH.

THE international congress held from Sept. 6th to 13th at Amsterdam and The Hague was the fourth concerned with industrial accidents and diseases. The permanent committee in recommending the series of meetings, the last of which was held at Rome in 1912, acted wisely, first in combining the two sections into one congress, and secondly, in selecting neutral, but central, territory for the representatives of nations to come together again. The countries sending official delegates were America, Australia, Austria, Belgium, Brazil, Britain, Bulgaria, Canada, Chili, Cuba, Czecho-Slovakia, Denmark, Finland, France, Germany, Holland, Hungary, Ireland, Italy, Japan, Norway, Poland, Spain, Sweden, South Africa, Switzerland, Roumania, Russia, and Turkey. The list is testimony to the spread of industrialism over the world with its post-war development in fresh centres.

Apart from official delegates many others were present whose reputations would alone have made the congress a notable gathering; among them may be mentioned Prof. B. Cuneo, France; Dr. Carozzi, International Labour Office, Geneva; Dr. L. Teleky, Vienna; Sir T. Oliver, Newcastle; Prof. F. H. Albee, U.S.A.; Prof. J. Glaister, Glasgow; Prof. L. Devoto, Italy; Dr. A. Trimble, Belfast; Prof. D. Koelsch, Germany; Mr. S. Alwyn Smith, Cardiff; Dr. W. Watkins-Pitchford, Johannesburg; Prof. E. L. Collis, University of Wales; and Prof. S. Kaplun, Russia. Great Britain was well represented, although the committee, under the presidency of Sir T. Oliver, which organised its membership and contributions had many difficulties to face and but few months to do its work; in this matter thanks are due to Dr. H. Menko, an able and indefatigable secretary, whose knowledge of Holland made him invaluable.

Holland is an entrancing and unique country to visit, which owes its very existence, lying below the sea-level, to the untiring activity of its population.

Its main industry, of course, is agriculture particularly applied to cattle and dairy produce, to market gardening and bulb-raising, but pottery is made at Delft, and diamonds are polished at Amsterdam, while Rotterdam possesses shipbuilding and docks second to none, and the Dutch glass industry flourishes. Hence those who attended the congress had opportunity of studying old problems in unfamiliar environment and of learning by inspection as well as by interchange of ideas.

The number and subject-matter of the papers contributed gave eloquent evidence of the scope of modern industrial hygiene. One criticism may be offered—the papers were too numerous and too diverse, and also too unequal in quality, to permit of adequate consideration and discussion. They numbered 147, and frequently time only allowed of their presentation at the meetings in the form of summaries too short to do them justice, particularly having regard to the diversity of languages employed.

Reference may be made to some of the more notable papers. Not the least interesting was an able résumé of the legal and ethical aspects of industrial insurance in Great Britain, prepared by Prof. Glaister, who, in concluding, stressed the need for compulsory medical examination when choosing a trade or profession—a subject which was further elaborated on the basis of German experience by Dr. W. Pryll. Dr. A. Kutschera pointed out the economic value of treatment of injuries; while Prof. Julliard summarised the different systems of dealing with financial claims for invalidity, whether by periodic payments, lump sums, or deferred claims. Sir T. Oliver in the address which we published last week related some recent achievements of industrial hygiene.

The treatment of accidental injuries, a matter of increasing importance to insurance companies, many of whom had sent their medical officers to the congress, was discussed from many aspects. Here Prof. Albee held his audience entranced with an exposition of bone-grafting by his new methods; Prof. L. Imbert made a valuable contribution on the treatment of fractures; Prof. Ch. Lenormant dealt with the treatment of wounds by suture; Dr. A. Oller described the Spanish institute where injured men are made fit to work again; Mr. Alwyn Smith pointed to the social and economic importance of dislocation of semilunar cartilages; Prof. Elsching handled the subject of industrial injuries to the eyes; and Mr. P. Mitchiner discussed injuries to the carpus and metacarpus and the value of stereoscopic X ray examination.

A link between accidents and diseases was provided by the relation between tuberculosis and occupational trauma which, Dr. F. Zollinger held, was difficult to prove satisfactorily, a view independently propounded by Prof. S. Diez, but Dr. Trimble produced evidence of a definite connexion. Closely associated in subject-matter were the papers by Prof. Collis summarising recent advances in knowledge on pneumonoconioses with special reference to silicosis, and by Prof. M. Sternburg on new views of this subject, and the less definite contribution by Prof. J. G. Sleeswijk. Other papers dealt with such occupational troubles as nystagmus, dermatoses, and tar cancer. The influence of overheated and damp atmospheres was dealt with from different viewpoints by Dr. C. S. Thomson and Dr. J. Torres Fraguas, which were reinforced by Dr. H. M. Vernon's evidence that invalidity increases as the mean temperature falls below or rises above an optimum of about 62° F.

The publication of the transactions in which these and the other papers will appear in full must be awaited before the full value to experts of the fruits of the congress can be appraised. But already the social success can be acclaimed. Throughout the week the hosts of the congress were perfect; their unstinted hospitality was notable, even for Holland; their tact, amounting almost to insistence, determined that national animosities should be suspended for one week at any rate, that national aloofness should be laid aside, and national friendships cemented. The cause of international meetings, as well as that of industrial hygiene, has thereby been placed deeply in debt to the Netherlands.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Irish Free State and the Medical Register.

IT is understood that, owing to the absence on holidays of many members of the Medical Consultative Subcommittee, there has been no meeting of that body since its interview with President Cosgrave on Sept. 9th (THE LANCET, Sept. 19th, p. 621). Conversations will probably be resumed early in October, and an attempt will be made to draft a scheme satisfactory both to the Government and to the Medical Subcommittee. Last week Dr. F. C. Purser, President of the Irish Medical Association and a member of the subcommittee, made a report to the Council of the Association of the negotiations up to the present. The policy of the Association in regard to the Medical Register was laid down at the annual meeting held in June, 1924, when the hope was expressed "that no change will be made in the system of medical registration in the Irish Free State which would interfere with the right at present possessed by medical men qualified in Ireland to practise in Great Britain and the Dominions." The representatives of the Association—Dr. Purser and Senator W. O'Sullivan—were thanked for their services and requested by the Council to continue to work for the policy of the Association as laid down in the above resolution.

The Senate Elections.

At the time of writing the count of first preferences in the Senate elections is not quite complete, though one can form, from the figures published, a fair estimate of the support given to the several candidates. It is expected that the quota for election will be about 15,000, and it is not likely that anyone will reach the quota on the first count. Of the medical candidates, so far, Mr. H. L. Barniville, an outgoing Senator, has done best, and of the others Sir Edward Coey Bigger has also done well. The remaining medical candidates appear in the following order, which may, however, be altered by further counts: Sir Arthur Chance, Mr. Denis Kennedy, Dr. A. MacBride, Dr. S. P. MacEnri, Prof. E. P. McLoughlin, Mr. P. McCartan. The medical candidates have been so far more fortunate than the legal. There were only two barristers among the candidates, and neither of them appears to have much likelihood of election.

MANCHESTER: POST-GRADUATE COURSES.—Post-graduate work, except for diplomas of public health and psychology, has not developed in recent years in Manchester. There is, perhaps, some feeling that a large influx of doctors from outside into the principal hospitals might damage the sound practical training which students receive. There have, however, been at several of the hospitals many courses of afternoon lectures open to and specially prepared for practitioners in the surrounding populous district. This year lectures are announced at Ancoats Hospital and at the Royal Infirmary. At Ancoats Hospital a series of lectures will be given by Mr. E. E. Hughes and Mr. Harry Platt on urinary symptoms and the treatment of fractures respectively. At the Infirmary members of the acting honorary staff take each one lecture on various subjects in turn, and there are also lectures by Dr. A. McDougall on epilepsy, Prof. W. L. Bragg on the nature of X rays, Prof. J. S. B. Stopford on the sympathetic nervous system, and by Sir William Milligan on foreign bodies in the food and air passages. This year the Lloyd Roberts Lecture will be given at St. Mary's Hospital, Whitworth-street, on Tuesday, Nov. 17th, by Dr. T. Watts Eden, on What We Can Do for the Unborn Child. This lecture is given at St. Mary's Hospital and at the Royal Infirmary alternately.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics of one English and two Scotch cities for 1924:—

Name of city.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population. All causes.	Tuberculosis.	Cancer.	Resp. Diseases with Influenza.	Death-rates per 1000 births. Neonatal mortality.	Infant mortality.	Maternity mort. from childbirth.
Sheffield	525,000	18·5	11·6	1·02	1·24	2·4	44	90	1·6
Edinburgh ..	426,305	19·7	14·8	1·33	1·60	2·5	36	89	6·0
Aberdeen.. ..	160,387	21·4	14·4	1·33	1·13	2·3	40	122	5·5

Sheffield.

Dr. Fred. E. Wynne reports as the outstanding feature of the year a very serious outbreak of encephalitis lethargica, which began towards the end of the first quarter and continued throughout the year. The incidence of the disease was heavier in Sheffield than in any other town. There were 837 notifications, in which the diagnosis was confirmed, and 40 deaths. Fifty-eight per cent. of the notifications were males, 42 per cent. were females, and 56 per cent. were under the age of 21. The after-effects of the disease have in many cases been tragic, and these after-effects are at present being investigated by the newly formed Medical Advisory Committee. The formation of this committee, say Dr. Wynne, is an event of first-rate importance to the city, mobilising, as it does, all classes of medical workers for the study of modern problems in preventive medicine. The committee will issue a detailed report dealing with possible factors in the causation and spread of the disease, and with its clinical manifestations, pathology, and after-effects.

A table deals with the prevalence of tuberculosis in the 17 towns of England and Wales having populations over 200,000, and brings out the fact that the Sheffield death-rate, both from respiratory and other forms of tuberculosis, is less than that of any other of these towns, and, in addition, that the percentage reduction in the death-rate from tuberculosis, under both headings, during the past ten years is the highest —namely, 42·6 per cent. for all forms of tuberculosis and 40 per cent. for respiratory tuberculosis. As Dr. Wynne says, these results are particularly gratifying in view of the nature of the principal industries of Sheffield. He refers to the better conditions under which various classes of grinding and abrasive industries are now carried out, and to the detection and treatment of early cases under the Silicosis Regulations as important factors in the improvement, but states that the conditions under which much of this industrial work is done are still profoundly unsatisfactory. Properly organised factories are needed to replace the dark insanitary "wheels" still in use. The work of the tuberculosis dispensary, where an enormous number of suspects and contacts are examined and supervised, is cited as perhaps the most important factor in the decline of tuberculosis in Sheffield. The King Edward VII. Sanatorium for surgical tuberculosis with its out-patient department is also responsible for the saving of many young lives and the prevention of crippledom.

Dr. Wynne states that the hospital isolation of measles and whooping-cough is more urgent than that of scarlet fever and diphtheria. Most cases of scarlet fever could be successfully treated at home and the hospital beds allocated to this disease could be usefully devoted to measles and severe cases of whooping-cough. The death-rate from infantile diarrhœa is less than one-fifth of what it was ten years ago, and Dr. Wynne gives as the most important factors in bringing about this decline "the wide substitution of dried for so-called fresh, but highly contaminated, milk" and the educative work of the child welfare centre. He is definitely of the opinion that until methods in the milk industry have been revolutionised "liquid milk should be banished from the dietary of infants." A table is given showing that the mortality-rate at ages 1 to 5 has improved during the last 25 years just as much as the infant mortality-rate, thus disproving the suggestion that the result of the efforts made is merely to postpone the deaths of feeble and degenerate infants from the first year to a slightly later period.

Overcrowding in the city is still deplorable. The waiting-list for municipal houses became so hopelessly unwieldy that for a time it was closed. Last year 1942 new houses were certified, the largest number since 1921. The list has now been reopened, and about 4000 new applicants have been registered. Of the 1942 new houses certified 305 were erected by the corporation.

The veterinary staff found 23 cows with tuberculous udders during the year in the 2848 stalls used for milch cows within the city. As regards the country milk coming into the city by road and rail, 950 samples were examined for tuberculous infection and 72 gave a positive result. In following up these tuberculous milks 47 cows with tuberculous udders were discovered. At 29 of the country farms visited no tuberculous udders were found, but in most of these cases cows had been sold during the period between the taking of the sample and the date of inspection. The latter period was shortened in many instances when the microscopical examination of the milk gave a positive result. Thus 20 country cows were condemned on the microscopical examination of the milk alone. Of the 75 cows proved to have tuberculous udders 58 were slaughtered, but 17 were sold by the owners and lost sight of.

Edinburgh.

Dr. William Robertson points out that the figures of density-rates for particular areas will be altered by the improvement schemes which are in hand. This applies to the wards in Edinburgh and Leith respectively, in which the death-rates are highest—namely, St. Giles and North Leith. Infant mortality has always been highest in the wards where the density is greatest and the one- or two-roomed houses predominate. The future progress of these wards after the improvement schemes are completed will be watched with much interest, says Dr. Robertson. Four arc lamps have been installed at the hospital for the treatment of surgical tuberculosis, and mercury-vapour lamps have been provided for the use of the child welfare clinics. Dr. Robertson is convinced that there is a great future for artificial light treatment and proposes to ask the Health Committee to extend the employment of artificial sunlight to other institutions. He thinks it will be found especially useful for children convalescing from various infectious and non-infectious illnesses. Greater encouragement is now given to the treatment of scarlet fever in the home. The hospital report shows, however, that the type of scarlet fever has recently become more severe. Thus the hospital mortality-rate, which was 1·9 per cent. in 1922, increased to 5·2 per cent. in 1923, and was 4·2 per cent. in 1924. Among the complications occurring there was an unexpectedly fatal type of nephritis. Edinburgh was the first town in this country to attempt the immunisation of school-children from diphtheria on a large scale. Twenty-six schools were taken in hand and 3507 children immunised without a single untoward event being recorded. The scheme is to be extended to the pre-school age, the period when the incidence of diphtheria is greatest. Measles and whooping-cough became epidemic in the later months of the year. Two fever-trained nurses were appointed to visit the homes and a large number of beds at Colinton Hospital were set aside for the reception of the more serious cases as well as of cases where the home circumstances were unsatisfactory. The tuberculosis death-rate showed a slight increase in 1924, and Dr. Robertson draws attention to the need for education in personal hygiene. For example, the citizens must be taught to appreciate that it is not so much the amount of food, but the correct selection and cooking of food that counts in building up and maintaining the body in good health and repair.

The report on the venereal diseases scheme shows that there is a progressive decrease in the percentage of patients who fail to complete their treatment. Thus in 1920 the percentage of defaulters was 40, in 1921 26, in 1922 it was 18·5, in 1923 15·6, and in 1924 11·9. Dr. David Lees, the V.D. medical officer, points out that this comparatively low percentage of 11·9 represents in the Edinburgh scheme a total of over 800 patients. The standard of cure adopted is high and many of these patients may be free from disease, but there are others who undoubtedly still have communicable disease and the problem involved requires careful consideration. Dr. Lees reports that the experiment of treating married women and children without specifically labelling them has been an unqualified success. Under this scheme 146 patients received in-patient treatment and subsequently put in 1452 attendances as out-patients. The percentage of those who failed to continue treatment was only 2, and more beds need to be allocated to this type of work. One of the drawbacks to the Edinburgh scheme is the lack of a hostel for unmarried girls who have contracted disease and lost their situations. The need for a V.D. centre in Leith has been recognised for long, but the Leith Hospital could not provide the accommodation required. Suitable premises have now been purchased quite close to the docks and the new clinic will be at work during 1925.

Dr. Robertson draws attention to the disparity between the rents at present paid by the slum-dwellers and the rentals of the cheapest of the new houses. Thus in the St. Giles Ward there are 1706 houses let at rentals of £5 to £10 per annum, while the cheapest of the new houses are rented at £12 and £15. Dr. Robertson goes on to bemoan the difficulty in convincing "many people who live in slums that a £15 house provided with such conveniences as electric light, gas boiler, hot-water system, washhouse, tub and sink, coal-cellar, drying green, and open air all round is in every possible direction worth £5 more than the dungeon-like slum devoid of almost every comfort that a human habitation should possess." There is a lack of skilled tradesmen in Edinburgh and houses have been kept waiting for plasterers. Dr. Robertson would like to see a chance given to mass production, and says, "there is surely much to be said in favour of a type of house that can be erected and made ready for habitation in six weeks time."

Progress has been made towards a cleaner milk-supply and a clean milk competition has been held. The amounts of designated milks at present sold daily in the city are as follows: Certified, 185 gallons; Grade A (tuberculin tested), 83 gallons; pasteurised, 2181 gallons, making a total of 2449 gallons. The daily consumption of undesignated milk amounts to 20,255 gallons. The cow population of the city numbers 4430, and among these the veterinary staff found 23 tuberculous udders and four cows with advanced tuberculosis. Mr. A. Gofton, the chief veterinary inspector, draws attention to one of the difficulties experienced by the owners of tubercle-free herds. If such an owner makes a purchase from any but a certified herd, he has no assurance that a cow which passes the test will also pass a second test applied after an interval of several months. The explanation is that the purchased cow may have been exposed to infection immediately before purchase and is therefore harbouring infection, which is at too early a stage to cause a reaction to the first test, but has time to develop between the first and second test. Mr. Gofton advises that when such an owner cannot make his herd self-supporting by breeding, he should segregate all new purchases for two or three months and then re-test.

Aberdeen.

Dr. J. Parlane Kinloch explains that his 1924 report is of the nature of a five-yearly survey. The report is a document of 200 pages and deals at some length with the methods which the health department has found most useful in preventing and curing disease, and also with the impending expansion of the statutory health services. It is only possible to refer to a few of the interesting points raised in this lengthy report, which will no doubt be of great value to the members of the town council and of all the other statutory and voluntary bodies interested in the health of the city. Under the heading "typhoid fever," Dr. Kinloch tells us that Aberdeenshire experience during the past 30 years suggests that this is now almost entirely a food-borne disease, due to the infection of milk or other foods by typhoid carriers, and that diminution in the number of typhoid carriers, due to the absence of the epidemic form of the disease, explains the diminishing amount of milk infection. As regards puerperal fever, Dr. Kinloch thinks it is of the utmost importance that routine bacteriological examination of expectant mothers about the seventh month should be carried out, with a view to determining what proportion of them have streptococci in the urethra or cervix. Methods of disinfection are to be modified. More visits will be paid in the case of infectious diseases nursed at home to secure immediate disinfection of infected articles, and some of the routine terminal disinfections will be discontinued.

In previous annual reports it has been shown that the death-rate from cancer is higher in the three east coast towns, Edinburgh, Dundee, and Aberdeen, than in the three west coast towns, Glasgow, Paisley, and Greenock. Dr. Kinloch, however, shows that when correction is made for age and sex of the populations of these six towns the difference in the cancer death-rate straightway disappears. Aberdeen experience shows that diabetic patients receiving insulin treatment fail to benefit to anything like the full extent owing to lack of adequate supervision and control. The city council in April, 1924, decided to make insulin treatment available for necessitous cases, and Dr. Kinloch thinks that the small additional expenditure involved in establishing a diabetic clinic, in order to see that the insulin treatment gives the best possible results, would be well worth while. Two years ago a biochemist was appointed at the laboratory of the City Hospital, and, in view of the results obtained by the application of methods of nutritional science to the dieting of the sick and the well, Dr. Kinloch hopes that the contemplated development of a nutritional laboratory will not be unduly delayed.

Some measure of improvement in the deadlock with regard to housing has to be recorded, as the result of the decision of the town council to erect 300 three-romed dwelling-houses on the Hilton estate. Dr. Kinloch urges the appointment of a town-planning committee. A town-planning scheme is called for by 1929 and the committee needs to get to work at once. In August, 1924, the council made a strong protest against the proposals in the Factories Bill, 1924, to remove the supervision of the sanitary condition of workshops from the sanitary authority to the Home Office, and urged the desirability, on the other hand, of transferring the sanitary supervision of factories from the Home Office to the sanitary authority. A considerable proportion of the report is taken up with the discussion of the joint hospital scheme and its relation to the University and to the municipal health services. Nearly every branch of the municipal health services is in need of extension and a capital expenditure of £227,000 is foreshadowed. The annual payment for interest and sinking fund is estimated to be equivalent to a rate of 2*d.* in the £, and the increased maintenance expenditure is estimated as equal to a rate of 8*d.* in the £. In addition to this expenditure the voluntary hospital service needs extension. The Royal Infirmary has 290 beds and is in a position to maintain them. An increase to 600 beds is said to be essential. It is thought that the required capital might be found, but that it would be difficult to obtain from voluntary sources sufficient money for the maintenance of 600 beds. The services of the municipal laboratory at present cover a wide ground, and Dr. Kinloch thinks it would be prejudicial to both parties if the University laboratories were to absorb the work of the municipal laboratory.

Dr. Kinloch is opposed to the farming out of municipal statutory services to voluntary bodies, and instances the inadequacy in Aberdeen of the schemes for dealing with venereal diseases and antenatal work. The existing state of knowledge with regard to light treatment is dealt with fully in the report, and Dr. Kinloch points out that even heliotherapy is possible in Aberdeen, with a fair degree of regularity, from the beginning of April to the end of October. The report concludes with coloured photographs of children receiving heliotherapy in Aberdeen on April 4th, 1925. The reasons for the excessive infant mortality-rate in Aberdeen are discussed and admitted to be somewhat obscure in the present state of knowledge.

SCHOOL MEDICAL SERVICE.

THE following are some of the school health statistics for Cardiff, Hull, and Leeds for 1924:—

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
Cardiff	30,305	—†	9,922	8,005	16·8
Hull	—†	—†	11,054	11,117	9·0
Leeds	—†	—†	19,309	53,006	20·1

* Excluding dental defects and uncleanliness.
† Not given.

Cardiff.

"The absolute limit of the capacity of the present staff and accommodation has been attained. . . . At the time of writing 622 cases are awaiting preliminary examination at the throat and nose clinic; 42 are awaiting operation for enlarged tonsils and adenoids; 237 are on the list for examination at the vision clinic; and 382 must take their turn for notice to attend the ordinary inspection and minor ailment clinic." So reports Dr. R. M. F. Picken, and nothing could further describe the inadequacy of provision for the school medical service. Only one dentist is employed in a vain endeavour to cope with a school population of 30,305. No provision as yet exists for physically defective children, though an orthopædic scheme has been approved by the board. Fifty-one partially blind and 27 partially deaf children are in attendance at ordinary elementary schools. No open-air schools are provided for delicate and pretuberculous children to the number of more than 200, and the provision for mental defectives is totally inadequate.

In a special report Dr. Picken outlines the minimum provision required to cope with school inspection, but states, "there is some concern at the expansion of this 'unremunerative department.'" On merely material grounds we think that "unremunerative" is entirely a misnomer. Many school medical officers have proved that inspection and early treatment of school-children directly pays for itself by increase of grant to the local authority, quite apart from the economic gain to the community, which should be apparent to any far-seeing authority.

Much good work has been done under great difficulties by Dr. Picken and his colleagues. Dr. H. L. Coulthard reports on the grave sequelæ of encephalitis in the few cases that have occurred in the district. He also points out how X ray treatment of ringworm has reduced the loss of school attendance from 98 days to 61 days on the average. On following up 287 cases of enlarged tonsils and adenoids, he finds that subsequent to operation there is marked relief from colds, sore-throats, earache, deafness, and otorrhœa, but that there is no evidence of increased innate intelligence apart from the increased vivacity and response due to improved health and hearing. In the course of the statutory school examinations for mental defectives, 77 were classed as mental defectives, 52 as imbeciles, and 18 as idiots; the proportion of imbeciles and idiots is so high as to suggest that the standard adopted is unusual.

Hull.

Dr. J. W. Fraser's report contains so much of special value that we are obliged to pass over the more ordinary topics to leave space for some unique features. There is in force at Hull the excellent and unusual practice of testing the vision and hearing of every child at the age of 6 years. The school for the physical defectives is conducted on somewhat exceptional but most beneficial lines, the objective being the care, and not only the safe-guarding, of those permanently crippled. Remedial treatment is given and 20 operations were performed there in the year. The orthopædic surgeon's report deals with the working of the school since its inception and deserves more extended notice. One of his conclusions is that if the children were brought early enough some types of defects would almost cease to exist. During the four and a half years that the school has been in operation 37 cases were discharged, and 70 per cent. of them are now practically fit. On this question of after-history Dr. Fraser gives authoritative statistics of those leaving the deaf and the mentally defective schools. Since 1914 32 children who have left the deaf school have been followed up, and 26 of them—i.e., over three-quarters of the whole number—are in some kind of work. Thirteen of these are earning between £1 and £2 a week, and only two are permanently unemployed. When we consider the useless and unhappy lot of the ordinary uneducated deaf person, this record is most significant and encouraging.

A similar careful account was kept of persons discharged from the mentally defective school in the ten years. Of 177 whose after-histories could be traced, 56 are in institutions, including 6 in Poor-law institutions; 60 are living at home without definite employment, but 33 of these are females, and are, no doubt, more or less engaged in housework; and 51 are in some kind of paid employment. Twenty-nine others are in precarious occupations, as, for instance, errand boys and newspaper boys, in which, however, many of them make a good sum weekly. A table gives details of the nature of the occupation and the wages earned. Dr. Fraser states that just over 10 per cent. of all discharged are earning over £1 a week. We can, perhaps, say that there are three groups: (1) Those in institutions or living uselessly at home. (2) Those who are following precarious or doubtful occupations. This would include the 29 boys selling newspapers, &c., some of the girls at home, and the persons earning less than 10*s.* a week. (3) Those who maintain themselves more or less satisfactorily. It is the second group who are difficult. The most economical alternative appears to be, to train them when older in institutions and then licence them out to work, as is done in the American system, or to transfer them to schools for older children where there is much manual training of vocational type. Subsequently they should be kept under strict supervision. In Hull "craft" classes for the dull and backward are successful and are being extended; we wonder if somewhat similar training might be tried on the higher grade and older mentally defectives. Dr. Fraser concludes, after a special inquiry, that if a boy, on discharge from a mentally defective school, has an intelligence quotient of 50 per cent. or more, with an annual average gain of six months or more in mental age, and if his character is good and he has some manual ability, he will probably do well. There is much value in this kind of investigation. The whole report is evidence of the enthusiastic work carried out by the school medical officer and his colleagues, supported by an enlightened authority.

Leeds.

In his full report Dr. A. Wear draws attention to the great increase in attendance at the seven school clinics—viz., 32,399 more than last year, which makes a grand total of 214,902 attendances during the year under review. Ringworm of the head, while showing a diminution, is still very prevalent. Ionisation for discharging ears is still under trial at the public dispensary. Notice is drawn to such conditions as flat-foot, accompanying malnutrition. At present no payment is made to the local hospitals for the operative treatment of tonsils and adenoids, but it is hoped that this will be altered in the near future. The recommendations of the Board of Education and the Ministry of Health *re* school closure have been carried out, and Dr. Wear suggests that more parental care is necessary to reduce the amount of infectious sickness. "A case of scarlet fever should be looked upon as a source of danger for at least a fortnight after return from hospital or disinfection of the home, and the child should not be permitted to mix with other children until after plenty of exercise in the open air."

Sir G. Newman, in his last report, stated that the average number of dental fittings is about 75 for every 100 children treated. In Leeds the proportion is 72 for every 100, and Dr. Wear regrets that the parents do not take more advantage of the excellent facilities for dental treatment which exist in the city. The dental tables show the amount of work done among the elementary school population; 48,858 were examined by the dentists. 31,609 required treatment, and 13,792 actually received treatment. On the other hand, in the secondary schools 4276 children were examined, 2402 required treatment, and only 103 accepted treatment. Such figures as these raise the question whether secondary school-children are not sacrificed at the shrine of respectability to the detriment of their physical welfare. Adequate provision is made for day-school education of mental defectives, but considerable difficulty is experienced in placing children who require residential treatment. Dr. Wear believes that increased manual education will considerably help in the solution of the employment outlook of mental defectives—a view which is rapidly gaining ground generally—and few will disagree with him when he states that more manual work in the cripple school will improve the wasted muscles and the stiffened limbs. The popular desire for decent living conditions is shown by the granting of prizes by the *Yorkshire Evening Post* for "mothercraft," "care of the teeth," and for essays on the latter subject. Many hundreds of mothers and children in the district entered for these and much good has resulted both directly and indirectly.

At the camp school, financed by the Leeds Elementary Schools Athletic Association, over 1400 children spent an enjoyable and profitable week; but a week is all too short to obtain the full increase in physical and mental vigour which invariably results from such a change.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 12TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 30; scarlet fever, 1510; diphtheria, 835; enteric fever, 106; pneumonia, 417; puerperal fever, 36; cerebro-spinal fever, 6; acute poliomyelitis, 19; acute polio-encephalitis, 2; encephalitis lethargica, 40; continued fever, 1; dysentery, 6; ophthalmia neonatorum, 114. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, 7 from measles, 3 from scarlet fever, 31 from whooping-cough, 11 from influenza, and 30 from diphtheria. There were 210 deaths of children under 2 years from diarrhœa and enteritis, as compared with 230, 218, 177, and 136 in the preceding weeks. In London itself the deaths from diarrhœa and enteritis in children under 2 years numbered 43, as compared with 38, 40, 28, and 20 in the preceding weeks; there were 8 deaths from diphtheria, 5 from whooping-cough, and 1 from influenza.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.: A. I. Sheldon and J. P. Shorten to the *President*, for R.N. Medical Store Depôt, Deptford.

Surg.-Lt. (D) D. C. Lamond to be Surg.-Lt. Comdr. (D).

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub-Lt. L. P. Spero to be Surg.-Lt.

Proby. Surg. Sub-Lt. A. T. G. Thomas to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Capt. H. T. Findlay is granted the temp. rank of Maj. whilst empld. as a Dep. Asst. Dir. of Pathology.

Capt. W. E. Tyndall is granted the temp. rank of Maj. whilst empld. as a Dep. Asst. Dir. of Pathology and Hygiene.

ARMY RESERVE OF OFFICERS.

Capt. A. L. Taylor, from R.A.M.C., T.A. Res., to be Capt.

Capt. I. Aubrey, late R.A.M.C., Spec. Res., to be Lt.

TERRITORIAL ARMY.

Maj. P. D. Warburton (Capt., Res. of Off.) resigns his commn. in the T.A.

ROYAL AIR FORCE.

F. B. C. L. B. Crawford is granted a short service commission as a Flying Officer for three years on the active list.

Flight Lt. F. E. Johnson is promoted to the rank of Squadron Leader.

Flying Officer L. P. McCullagh is promoted to the rank of Flight Lt.

Flight Lt. J. S. Wilson is transferred to the Reserve Class D.2.

INDIAN MEDICAL SERVICE.

Capts. J. Findlay, W. C. Spackman, N. M. Mehta, and C. H. P. Allen to be Majs.

Bhalchandra Kondopant Phatak and Gurbakhsh Dhamrait Rai to be Temp. Lts.

The King has approved the retirement of Col. F. L. Blenkinsop.

Lt.-Col. J. McPherson, civil surgeon, Peshawar, and Agency Surgeon in the Khyber, has been appointed Residency Surgeon, Mysore, vice Lt.-Col. R. Standage, proceeding on leave pending retirement. Lt.-Col. H. A. J. Gidney has resigned his seat on the Legislative Assembly. Lt.-Col. J. W. McCoy, civil surgeon, Lakhimpur, has been transferred to Sylhet. Maj. D. L. Graham, civil surgeon, Sadiya Frontier Tract, has been transferred to Sylhet. The following are granted leave: Capt. G. D. Malhoutra, Indian Station Hospital, Allahabad; Maj. A. C. Anderson, Jail Department, Madras; and Lt.-Col. R. P. Wilson, Officiating Surgeon-General with the Bengal Government.

The Future of the Service.

With reference to the optimistic views which have appeared in THE LANCET with regard to the future of the I.M.S., it is interesting to note that only a few weeks ago the editorial columns of the *Pioneer*, which represents more or less the official view of Indian affairs, had the following remark: "Sir James Roberts, who had an exceptionally prosperous career in India, is strongly of opinion that the future of his old service, the I.M.S., is promising for Europeans. In a letter to the *Times*, indeed, he makes a general protest against ex-officials dissuading young Englishmen from entering the Indian Services, where, according to Sir James, 'a fine career awaits them.' As for the I.M.S., it provides 'just the life to suit an Englishman—responsibility, position, sport, and adventure.' The fact remains that there is no desire shown by young doctors at home to enter this fascinating service, while European members of the I.M.S. actually serving in India, so far from sharing Sir Robert's enthusiastic optimism, apparently consider that a service which has done magnificent work for the people of this country is doomed."

In a Royal Warrant recently signed it is laid down that in the interests of the Service an officer of the Indian Medical Service, holding the appointment of Director, I.M.S., in India, shall be placed on the retired list on attaining the age of 60. This decision involves a reversion to an arrangement which was altered some time ago. On attaining the age of 57 a Major-General of the I.M.S. was compelled to retire by the change referred to, but now, when he becomes Director of Military Services, he will not be placed on the retired list until he reaches the age of 60.

The Government of Madras have approved of the proposal of the Principal of the School of Indian Medicine to give stipends to women students of the School. The stipends will be granted at the rate of Rs.20 per mensem, and the number of stipends awarded in one year will be subjected to a maximum of five. The stipendiaries will be supplied with books and instruments at the cost of the Government, and, on the completion of the course, they are liable to serve the Government, if required, for a period of not less than five years.

Sanction has been accorded, with approval of the Secretary of State, to the employment of six specialists in medicine with specialists pay at Rs.75 a month. Sanction has also been accorded to the employment of one additional specialist in surgery, and one specialist in electrical science, in the Waziristan district.

TINNED FOOD IN THE BRITISH ARMY.

Recent Army Orders in reference to messing enjoin that all tins containing food must be thoroughly examined and none accepted which bears traces of rust round the joints or which is badly dented. Emphasis is laid on the fact that tinned salmon, herrings, potted meat, and fish-paste will quickly become unfit for consumption if left in the tins after they have been opened. It is also pointed out that the necessary ingredients for making fish-cakes and similar dishes should be prepared before the tins containing the fish are opened, and that these dishes, when prepared, should be cooked without delay.

"Audi alteram partem."

THE CONTROL OF VENEREAL DISEASES.

To the Editor of THE LANCET.

SIR,—Some four years' experience in the industrial towns and county districts of Lanarkshire has convinced me that it is in our large cities that the solution of the venereal diseases problem must be found, and that the health of rural communities can best be protected by the effective control of these diseases in urban areas. On p. 43 of the Annual Report of the Scottish Board of Health for 1920 the following statement is to be found: "When in every district in the country a patient can secure treatment with reasonable convenience and due promptitude, the Board will be free to turn to . . . the problem of considering whether in the interests of the community it should not be made a matter of compulsion that persons contracting these diseases shall have recourse to treatment and shall continue in attendance for a period sufficient to ensure full results therefrom." To-day adequate facilities for treatment are provided. Is it not time that something more was done to stamp out venereal disease?

Treatment has done much, and venereal diseases are rightly believed to be diminishing; but those intimately connected with clinical work best know how unsatisfactory and inadequate is our control over them. The infected individual, the uninfected public, the qualified practitioner, the unqualified quack, and, last but not least, public health authorities—all these are playing a part in postponing the day of victory in the antivenereal campaign. Some infected persons never come for treatment at all because their symptoms are slight and tend to disappear spontaneously; others abandon treatment as soon as it has removed the obvious manifestations of the disease; few report early enough. All these classes of case are liable to pass on the disease to others, and interrogation reveals that the average male patient is even ignorant of the uses of the simplest prophylactic measures. These are some of the shortcomings of the patient himself; a further obstacle to his proper treatment is the unenlightened state of public opinion. Attendance at a clinic by venereal sufferers is a public duty designed to protect the health of the community, and the performance of this duty must be encouraged. There is something to be said for the idea of doing away altogether with the term "venereal," inventing some fresh name, proclaiming it as a deadly disease, and treating the victims as in-patients in isolation hospitals.

Gonorrhœa is still far too lightly regarded by many medical practitioners, who delay sending patients to a clinic until the ordinary palliatives (and provocatives) have failed, and, notwithstanding the Regulations of 1917, quack treatment of venereal disease has not been completely stamped out. There are some unscrupulous persons who are evading the law; and this reflection naturally leads to the fifth class of offender—those responsible for public health administration. Failure to prosecute the first detected case of unqualified treatment is short-sighted leniency, because by its very nature the offence is one which but seldom comes to light. Slackness in giving effect to the provisions of the Mental Deficiency Act of 1913 allows feeble-minded females to indulge in sexual promiscuity and to spread venereal disease. It is also regrettable that the civil authorities should tolerate without protest the discharge from the Navy of uncured cases of gonorrhœa, and condone the system which virtually makes the acquiring of gonorrhœa grounds for discharge from the Service. In our prisons, too, full advantage is not being taken of the opportunity to treat by modern methods prisoners with latent or active venereal infection.

The question of what further measures are needed to hasten the ebb of the tide of venereal disease seems to divide medical opinion. All are agreed on the desirability of raising the general standard of sex morals. For the rest, the hope of many seems to lie in further advertisement of the necessity for early treatment and of the provisions made therefor, in a higher standard of treatment of gonorrhœa, and in good advice given to patients at clinics regarding the prevention of marital and congenital infection. Short of applying legal compulsion to infected persons, is there anything further that might be done to prevent the spread of venereal disease? In some cases defaulting patients might be persuaded to resume treatment if visited in their homes by plain-clothes members of the sanitary staff; the prohibition of the sale by chemists of ad hoc preventive disinfectants might, with suitable safeguards, be removed; the sale of drugs or appliances of known or reputed value in treatment might well be prohibited except on qualified prescription, and more thorough supervision by local authorities of mentally defective girls and moral imbeciles, with routine examination for disease on admission to institutions, is urgently required. All these measures will doubtless tend to a slow reduction of venereal disease. But if gonorrhœa and syphilis are ever to cease to be endemic something more than our present methods is required. The essential problem is to get at a comparatively small number of infected men and women in our big cities who are responsible for keeping the disease going. Careless of everything they go on spreading the poison. How are they to be dealt with?

In Scotland opinion has got so far as discussing what form notification should take; but notification is relatively worthless by itself unless the onus of notifying is laid on the infected person and unless failure to undergo satisfactory treatment can be adequately penalised. Any attempt to punish those who discontinue treatment, without also penalising failure to report symptoms, would defeat the object we have in view. To compel infected persons to present themselves for treatment may be contrary to common law, but, if so, it is obvious that the law can be altered. So long as we go on dealing with only those who come voluntarily for treatment to our clinics, and so long as a big percentage of these patients leave off treatment while still potential sources of infection,

5. It is consequently necessary, as I have already pointed out, that the after-care of the patients be continued sometimes for one or two months. During this time the characteristic symptoms of the disease are gradually disappearing and a general improvement in health becomes manifest.

Let us consider now the action of smalarina. Since this compound is not a febrifuge, it is hardly reasonable, for all practical purposes, to expect that the fever should abate after its administration. I have never maintained the febrifuge action of smalarina. Dr. Low and Dr. Gregg have done well in giving quinine in their cases, but quinine would have not been either advantageous or necessary in the subacute, chronic, masked, and latent malaria forms. Although no clinical control was carried out by using quinine alone, the rapid recovery which the patients made on the administration of quinine, and the rapid diminution of the splenic enlargement in the cases reported, should surely cause some surprise if that effect is attributed to the quinine. Either the recovery is a symptomatic one, manifested in the cessation of fever and the disappearance of the parasites from the peripheral blood-stream, but leaving the patient still infected with malaria, or it may be considered as sterilisation with a rapid improvement of the subject and rapid diminution or disappearance of the splenic enlargement. In the first alternative the quinine may really be the effective factor, in the other this drug may not play any part, but we may be dealing with the self-protective action of the tissues, as in recoveries which are spontaneous or are provoked by a biological stimulus. If Dr. Low and Dr. Gregg follow up their three patients they will discover that the splenic enlargement has entirely disappeared and that the fever will not recur. This result never occurs after such brief treatment with quinine. The whole malaria problem belies such optimism.

To obviate certain mistakes in such clinical experiments I should like to make the following points clear. When we treat a patient with smalarina, we must forget our ideas on the pharmaceutical therapy, particularly on the usual method of treatment. The practitioner usually takes note of the most evident symptom, the fever, which indeed does not represent the disease (nor when it disappears has the disease been eradicated), but he does not take note of the deep-seated constitutional lesion which is produced by an hereditary defect. The new biological therapy produces an organic reaction occurring at various times according to the organism in question. It represents, therefore, a result of a natural law and arises when Nature wishes. If we treat a patient with the new method and expect some determined results at a fixed time, that means we claim that our law is superior to natural law.

By limiting himself to observation of results the malariologist will not only see his patient's recovery but also a series of very interesting and unexpected phenomena, as did those colleagues who have obtained fortunate results by following the method according to the rules that I have suggested. Treatment will not be successful if carried out under wrong conditions. The bad results, however, that we obtain in these cases appear to be only transitory, and the proof of this lies in the fact that we clearly see the advantages of the new method when we follow up the patients for some time after treatment. Chemical therapy, as rapid as it is ephemeral, has made us accustomed to expect some prompt results, and when these are not forthcoming we say the therapy has failed. If, however, a therapeutic method can produce an organic reaction (feverish reaction) after 10–15 days of treatment and a sterilisation after one or two months, it is evident we are dealing with something which is not a "pharmaceutical" treatment. Until we have thoroughly and at length experimented with this "something," we cannot say it has failed to produce the desired results.

The cases and method of application of Dr. Low and Dr. Gregg do not conform to the postulates I have established—namely, a rigorous application of some therapeutic rules that I have published after many years of diligent research.

I am, Sir, yours faithfully,

Rome. GUIDO CREMONESE.

JOURNALS FOR MEDICAL MISSIONARIES.

To the Editor of THE LANCET.

SIR,—May I, through your columns, make known the need of medical literature for members of the medical profession who work in hospitals scattered over the world? I have at the moment three requests for THE LANCET, and would gladly supply addresses to which such literature should be sent regularly.

I am, Sir, yours faithfully,

JANET BRADBURY,
S.P.G. Sec. for Medical Literature.

Darenth House, Sandgate, Kent, Sept. 10th, 1925.

MACLEAN'S "LAG" BLOOD-SUGAR CURVE.

To the Editor of THE LANCET.

SIR,—MacLean has specially called attention to a peculiar disturbance of blood-sugar regulation characterised by what he calls the "lag" blood-sugar curve.[1] By this name he denotes a condition in which, when a sugar-tolerance test is performed in the way he describes,[2] blood-sugar rises above the normal threshold value of about 0·18 per cent. within half an hour after the ingestion of sugar, but goes down again very quickly and is quite normal within two hours (or, in the old, within three hours) after the ingestion of sugar. A more or less important glycosuria is also produced.

A point of great practical importance is the prognostical significance of this type of blood-sugar curve. For the present, MacLean takes the view that "a patient who gives this lag type of curve, but *who shows no delay in the return of blood-sugar to normal after ingesting sugar,* is probably not suffering from a defect which is likely to prove prejudicial to his carbohydrate metabolism."

I have recently seen a case which has, I believe, some interest from this prognostical point of view.

J. M., aged 66. Thirty-six years ago sugar was found in the urine. A slight food restriction banished the glycosuria, which was constantly found absent so long as the food restriction was maintained. A few years later both food restriction and urine examinations were discontinued until 1918, when a urine analysis was again performed and sugar was found. Since then the analyses have been frequently repeated and glycosuria has always been found, varying from traces up to 3·0 per cent. Changes in glycosuria have been found to correspond with those in the diet. Food restriction was never very serious, bread and potatoes, for instance, being never omitted. No diabetic symptoms were noticed at any time. The patient has always felt very well and vigorous. At present he is an exceedingly healthy-looking old gentleman, is not, and has never been, over weight, and his blood pressure is 120/75.

A blood-sugar tolerance test, with 50 g. sugar, performed on Sept. 2nd, 1925, gave the following figures:—

	Blood-sugar per cent.		Urine sugar per cent.
Fasting	0·11	....	Nil
30 minutes after ingesting sugar	0·205	....	—
2¼ hours " " "	0·10	....	1·3

The main interest of this case lies in the fact that a blood-sugar regulation disturbance of the "lag" curve type has existed for at least 36 years, neither being the cause of any clinical disturbance except glycosuria, nor showing any tendency to pass into a true diabetes, despite the fact that no serious diet has ever been kept and that, probably, glycosuria has constantly been present, except for a short number of years after it was first discovered. This

so is therefore strongly in favour of MacLean's timistic opinion on the prognostic significance of e "lag" blood-sugar curve. It is also of interest remark that in this case of non-diabetic dextros- ia, as, probably in all those of the same type, anges in diet are followed by changes in the daily cretion of sugar of the same type as those met ith in true diabetes, in opposition to what is seen typical renal glycosuria and other non-diabetical ycosurias. This fact emphasises the importance of rforming sugar-tolerance tests, with blood-sugar terminations, in all cases of glycosuria in which the abetic nature of this symptom is not quite evident, ven when it may seem possible to exclude renal ycosuria and other non-diabetic glycosurias, such s lævulosuria, pseudo-lævulosuria, &c.

---

LUMINAL IN EPILEPSY.

To the Editor of THE LANCET.

SIR,—I have read, with great interest, the letter of r. Hildred Carlill in THE LANCET of Sept. 19th on case of luminal poisoning. For the last three years have had the opportunity of studying the action of uminal and I have found that, except in cases of pilepsy, in which cases the number of fits was reduced ery considerably, the drug was very disappointing. he dose we give here is 2 gr. twice daily. Larger oses when tried as a sedative or hypnotic have not iven satisfactory results, in fact very disappointing, s the patient becomes stuporous, restless, and in few cases the sphincters were relaxed. Gradual ecrease in the dose of luminal is essential, but sudden cessation may cause the same symptoms s a large dose.

I am, Sir, yours faithfully,
S. GROSSMAN,
Assistant Medical Officer, Cardiff City Mental Hospital.

Sept. 22nd, 1925.

Medical News.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The Fellowship of Medicine will hold a series of lectures on Tuberculosis in the Lecture-room of the Medical Society, 11, Chandos-street, in October. The opening lecture will be delivered on Oct. 12th at 5.30 P.M. by Dr. L. S. Burrell on Tuberculosis from the Physician's Viewpoint. There is no fee for this series, and all members of the medical profession will be welcomed. During October there will also be held the following course: Diseases of the Throat, Nose, and Ear at the Central London Throat, Nose and Ear Hospital (an operative surgery class will also be held); a course in Tropical Medicine, consisting of eight clinical demonstrations on Tuesdays and Thursdays; a combined course in Diseases of Children at the Paddington Green Hospital, Victoria Hospital, and Children's Clinic; a course in Urology at St. Peter's; and a course in Dermatology at St. John's. Copies of any syllabus, together with the Fellowship programme, may be obtained from the Secretary, at 1, Wimpole-street, W. 1.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—The distribution of prizes to students by Sir Herbert Waterhouse will be made in the out-patients' hall of the hospital on Monday, Oct. 5th, at 3.30 P.M.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—On Monday, Oct. 5th, and Tuesday, Oct. 6th, 10 A.M. to 1 P.M., first-year students of the Faculty of Medical Sciences will be received by the Senior Tutor, the Dean of the Faculty, and the Sub Dean. On Monday, Oct. 5th, 2.15 to 4 P.M., students of the Faculty of Medical Sciences other than first-year will be received; on the same day at 3.15 P.M. candidates for the Diploma of Public Health will be received by Mr. Delafield, Acting Head of the Department. The new buildings for anatomy, anthropology, embryology, histology, and physiology, provided by the gift of the Rockefeller Foundation of New York, are now in full use. The list of public lectures includes six on the Study of Man by Prof. G. Elliot Smith and Dr. C. F. Sonntag, and one on the Photochemistry of Vision by Prof. Fritz Weigert of the University of Leipzig. There will also be eight lectures on the Physiology of Hearing and Vision, which will be given by Mr. R. J. Lythgoe on Mondays and Wednesdays at 5 P.M., starting on Oct. 12th.

LECTURES AT KING'S COLLEGE.—A course of ten lectures on the Histology of Nerve Tissues and Paths of Conduction in the Central Nervous System will be given by Dr. C. Da Fano at King's College, at 5 P.M., on Thursdays during the present session, beginning on Oct. 8th.

THE People's League of Health has awarded a travelling scholarship to Miss Alice Gilby, who is a second-year medical student at the London School of Medicine for Women.

AT the third annual general meeting of the British Provident Association for Hospital and Additional Services, held on Sept. 21st, a resolution was passed expressing the Association's appreciation of the services of the late Dr. J. F. Gordon Dill in the cause of the voluntary hospitals of this country.

IMPERIAL SOCIAL HYGIENE CONGRESS. — The British Social Hygiene Council, which was lately the National Council for Combating Venereal Diseases, is organising a congress to be held at Wembley from Oct. 5th to 7th under the presidency of Sir Auckland Geddes. Distinguished representatives of the Dominions have agreed to take part in the discussions, and addresses will be given by Mr. L. S. Amery (Colonial Secretary), Mr. Neville Chamberlain (Minister of Health), and Lord Willingdon. The problem of venereal disease as it affects the Empire will be fully discussed.

CORK DENTAL HOSPITAL.—The honorary staff of this hospital, which forms part of the North Infirmary, have resigned in a body on a number of grounds. The staff complain, generally, that the committee of management have "persistently ignored" their recommendations, even upon matters regarding which they are especially qualified to advise, and, more specifically, that they were not consulted upon the opening of the hospital at night, and that two salaried appointments were recently made in face of their opposition. The honorary staff has been invited to a conference with the committee of management and has been asked to continue duty in the meantime.

LONDON MEDICAL EXHIBITION.—From Oct. 5th to 9th the medical profession will again have an opportunity to taste, see, or handle the products of our leading drug houses and scientific manufacturing firms at the Central Hall, Westminster, S.W. The London Medical Exhibition, which is open to medical men only, will comprise the most recent organo-therapeutic, bacteriological, and pharmaceutical remedies and prophylactics; electro-therapeutic apparatus; scientific dietary; surgical instruments; hospital furniture and medical appliances, diagnostic material, and apparatus; pathological and physiological apparatus; artificial limbs, aids in invalidity and deformity; sick-room requisites; natural and artificial hydrotherapy; professional literature; hygienic clothing, and so forth. Invitation cards can be obtained from the secretary of the exhibition, 191-200, Bishopsgate, London, E.C., or at the Central Hall during the exhibition. The exhibition is exclusively for members of the medical profession.

DONATIONS AND BEQUESTS.—By the will of the late Mrs. Catherine Ada Potter, of Llandaff, the testatrix left £1000 to Cardiff Royal Infirmary "to endow a bed in a ward to be called the Catherine Ward," and £100 in addition "on condition my grave is kept in good order and looked after by such infirmary." Among other bequests she left £100 to the Cardiff Blind Institution.—The Manchester Royal Infirmary has received £10,000 on account from a legacy by the late Miss Ann Russell.—Mrs. Ellen Margaret Smith, Aughton, Lancashire, who left £12,014, besides other bequests, including certain sums to her husband, left on his death £500 each to the School for Indigent Blind, Liverpool, the Hospital for Women, Liverpool, and the Ormskirk District Nursing Association.—The Christie Hospital, Manchester, has received a donation of £1000 from Mrs. Taylor, of Whalley Range, to endow a bed in memory of her husband and brother-in-law, Mr. Henry Marsland Taylor and Mr. James Henry Taylor, two of Manchester's oldest solicitors.

5. It is consequently necessary, as I have already pointed out, that the after-care of the patients be continued sometimes for one or two months. During this time the characteristic symptoms of the disease are gradually disappearing and a general improvement in health becomes manifest.

Let us consider now the action of smalarina. Since this compound is not a febrifuge, it is hardly reasonable, for all practical purposes, to expect that the fever should abate after its administration. I have never maintained the febrifuge action of smalarina. Dr. Low and Dr. Gregg have done well in giving quinine in their cases, but quinine would have not been either advantageous or necessary in the subacute, chronic, masked, and latent malaria forms. Although no clinical control was carried out by using quinine alone, the rapid recovery which the patients made on the administration of quinine, and the rapid diminution of the splenic enlargement in the cases reported, should surely cause some surprise if that effect is attributed to the quinine. Either the recovery is a symptomatic one, manifested in the cessation of fever and the disappearance of the parasites from the peripheral blood-stream, but leaving the patient still infected with malaria, or it may be considered as sterilisation with a rapid improvement of the subject and rapid diminution or disappearance of the splenic enlargement. In the first alternative the quinine may really be the effective factor, in the other this drug may not play any part, but we may be dealing with the self-protective action of the tissues, as in recoveries which are spontaneous or are provoked by a biological stimulus. If Dr. Low and Dr. Gregg follow up their three patients they will discover that the splenic enlargement has entirely disappeared and that the fever will not recur. This result never occurs after such brief treatment with quinine. The whole malaria problem belies such optimism.

To obviate certain mistakes in such clinical experiments I should like to make the following points clear. When we treat a patient with smalarina, we must forget our ideas on the pharmaceutical therapy, particularly on the usual method of treatment. The practitioner usually takes note of the most evident symptom, the fever, which indeed does not represent the disease (nor when it disappears has the disease been eradicated), but he does not take note of the deep-seated constitutional lesion which is produced by an hereditary defect. The new biological therapy produces an organic reaction occurring at various times according to the organism in question. It represents, therefore, a result of a natural law and arises when Nature wishes. If we treat a patient with the new method and expect some determined results at a fixed time, that means we claim that our law is superior to natural law.

By limiting himself to observation of results the malariologist will not only see his patient's recovery but also a series of very interesting and unexpected phenomena, as did those colleagues who have obtained fortunate results by following the method according to the rules that I have suggested. Treatment will not be successful if carried out under wrong conditions. The bad results, however, that we obtain in these cases appear to be only transitory, and the proof of this lies in the fact that we clearly see the advantages of the new method when we follow up the patients for some time after treatment. Chemical therapy, as rapid as it is ephemeral, has made us accustomed to expect some prompt results, and when these are not forthcoming we say the therapy has failed. If, however, a therapeutic method can produce an *organic reaction* (feverish reaction) after 10–15 days of treatment and a sterilisation after one or two months, it is evident we are dealing with something which is not a "pharmaceutical" treatment. Until we have thoroughly and at length experimented with this "something," we cannot say it has failed to produce the desired results.

The cases and method of application of Dr. Low and Dr. Gregg do not conform to the postulates I have established—namely, a rigorous application of some therapeutic rules that I have published after many years of diligent research.

I am, Sir, yours faithfully,

Rome. Guido Cremonese.

JOURNALS FOR MEDICAL MISSIONARIES.

To the Editor of The Lancet.

Sir,—May I, through your columns, make known the need of medical literature for members of the medical profession who work in hospitals scattered over the world? I have at the moment three requests for The Lancet, and would gladly supply addresses to which such literature should be sent regularly.

I am, Sir, yours faithfully,

Janet Bradbury,
S.P.G. Sec. for Medical Literature.

Darenth House, Sandgate, Kent, Sept. 19th, 1925.

MACLEAN'S "LAG" BLOOD-SUGAR CURVE.

To the Editor of The Lancet.

Sir,—MacLean has specially called attention to a peculiar disturbance of blood-sugar regulation characterised by what he calls the "lag" blood-sugar curve.[1] By this name he denotes a condition in which, when a sugar-tolerance test is performed in the way he describes,[2] blood-sugar rises above the normal threshold value of about 0·18 per cent. within half an hour after the ingestion of sugar, but goes down again very quickly and is quite normal within two hours (or, in the old, within three hours) after the ingestion of sugar. A more or less important glycosuria is also produced.

A point of great practical importance is the prognostical significance of this type of blood-sugar curve. For the present, MacLean takes the view that "a patient who gives this lag type of curve, but *who shows no delay in the return of blood-sugar to normal after ingesting sugar*, is probably not suffering from a defect which is likely to prove prejudicial to his carbohydrate metabolism."

I have recently seen a case which has, I believe, some interest from this prognostical point of view.

J. M., aged 66. Thirty-six years ago sugar was found in the urine. A slight food restriction banished the glycosuria, which was constantly found absent so long as the food restriction was maintained. A few years later both food restriction and urine examinations were discontinued until 1918, when a urine analysis was again performed and sugar was found. Since then the analyses have been frequently repeated and glycosuria has always been found, varying from traces up to 3·0 per cent. Changes in glycosuria have been found to correspond with those in the diet. Food restriction was never very serious, bread and potatoes, for instance, being never omitted. No diabetic symptoms were noticed at any time. The patient has always felt very well and vigorous. At present he is an exceedingly healthy-looking old gentleman, is not, and has never been, over weight, and his blood pressure is 120/75.

A blood-sugar tolerance test, with 50 g. sugar, performed on Sept. 2nd, 1925, gave the following figures:—

	Blood-sugar per cent.		Urine sugar per cent.
Fasting	0·11	....	Nil
30 minutes after ingesting sugar	0·205	....	—
2¼ hours ,, ,, ,,	0·10	....	1·3

The main interest of this case lies in the fact that a blood-sugar regulation disturbance of the "lag" curve type has existed for at least 36 years, neither being the cause of any clinical disturbance except glycosuria, nor showing any tendency to pass into a true diabetes, despite the fact that no serious diet has ever been kept and that, probably, glycosuria has constantly been present, except for a short number of years after it was first discovered. This

case is therefore strongly in favour of MacLean's optimistic opinion on the prognostic significance of the "lag" blood-sugar curve. It is also of interest to remark that in this case of non-diabetic dextrosuria, as, probably in all those of the same type, changes in diet are followed by changes in the daily excretion of sugar of the same type as those met with in true diabetes, in opposition to what is seen in typical renal glycosuria and other non-diabetical glycosurias. This fact emphasises the importance of performing sugar-tolerance tests, with blood-sugar determinations, in all cases of glycosuria in which the diabetic nature of this symptom is not quite evident, even when it may seem possible to exclude renal glycosuria and other non-diabetic glycosurias, such as lævulosuria, pseudo-lævulosuria, &c.

we are merely playing the part of public health quacks—treating the symptoms but neglecting the cause of what is both a social and a physical disorder. Clamant as are the calls for housing and economic improvements, and desirable as is the raising of the general standard of sex morals, it should be recognised that venereal disease need not remain with us until Utopia arrives. It is a question not of morals but of medicine. Disease is merely an unfortunate accidental accompaniment of venery, and such accidents will *not* happen in well-regulated communities. The problem of sexual immorality is not identical with that of venereal disease, and we must take the risk of making the world safe for profligacy. Venereal disease is the most easily preventable of all diseases, and it should not be beyond the power of medical science to stamp it out. The virus is short-lived outside the body; infection is possible only by close contact. Early thorough treatment prevents the disease being passed on to others. We have the knowledge; all that is required is the will and the courage to make practical use of that knowledge.

Let the transmission of venereal diseases be made an offence against the law of the land. Let each individual case of fresh infection be followed up ruthlessly and inquisitorially, with as much thoroughness and as much determination as is shown now in eradicating other and less harmful diseases. To do less is wicked wastefulness and cowardly procrastination.—I am, Sir, yours faithfully,

ROBERT FORGAN, M.D., D.P.H.,
Executive Medical Officer, Lanarkshire
Joint V.D. Scheme.

Sept. 14th, 1925.

⁂ In Edinburgh the percentage of patients who fail to complete their treatment at V.D. centres fell from 40 in the year 1920 to 11·9 last year. Among certain classes of patients the leakage was very small indeed, as may be seen from the report on p. 670.—ED. L.

RHEUMATIC INFECTION IN CHILDHOOD.

To the Editor of THE LANCET.

SIR,—In the investigation of the problem of rheumatism which is engaging so much attention at the present time there appears to be a danger lest the fundamental nature of the disease should become obscured. While the possible influence of some "germ" cannot be ignored, it is essential that there should be clear recognition of certain features of rheumatism in its broadest sense which are constant, easily detected, and very suggestive. Sufferers from rheumatic affections have a temperature that is normally subnormal, they have skins which are habitually inactive, and they are liable to short attacks of fever always accompanied by increase of pain and acid sweating. These attacks may be slight and overlooked, or they may present the classical symptoms of acute rheumatic fever. Rheumatic fever left to itself burns itself out in the course of a few weeks, the more severe the symptoms the sooner they disappear; though the illness leaves permanent heart-scarring it must be credited with a tendency to self-cure.

By physical measures this self-curative process may be stimulated and hastened. If artificial fever and sweating are induced there is a temporary increase in the severity of the symptoms quickly followed by rapidly progressive relief. That this view of rheumatism is not merely theoretical is abundantly proved by the results of treatment upon these lines; chorea, "rheumatic fever," subacute and chronic rheumatism in child and in adult yield to the application of moist warmth, and consequent pyrexia and sweating without the use of any drug. It would seem that the basic factors in rheumatism are an error of metabolism leading to the storage of lactic acid compounds in the tissues, and a failure of the skin to expel this poison except under the stimulus of fever.

This conception of the disease suggests t
tion is to be sought in measures th

skin action and freedom from the depres·ing influence of cold, damp, and malnutrition. Other factors may play a part in some cases, but a study of the problems of prevention and cure that does not take into account the aberration of skin activity and lactic acid metabolism is likely to be sterile or misleading in its results.
I am, Sir, yours faithfully,
C. E. SUNDELL.

Queen Anne-street, W., Sept. 21st, 1925.

To the Editor of THE LANCET.

SIR,—The meaning of "poverty" in the dictionary is given as want, necessity, defect, and its derivation is from the Latin pauper. Dr. R. Miller (THE LANCET, Sept. 19th, p. 626) applies this term to the working or artisan class, an indictment that calls for immediate action on the part of the community, if what Dr. Miller says is correct. What I tried to emphasise was that the majority of post-rheumatic and post-choreic heart cases are to be found in those who partake of neither of the great lime-bearing foods—milk and eggs—amongst the poor, because they cannot afford them, and amongst the well-to-do because of a great dislike to those foods.

I am, Sir, yours faithfully,
Swansea, Sept. 19th, 1925. G. ARBOUR STEPHENS.

PERSISTENT DIARRHŒA IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—One of the most serious complications of a pulmonary, peritoneal, or general tuberculosis is persistent diarrhœa. This enteritis is not necessarily tuberculous; it may be in part or altogether septic, but in any case it is a happening of evil omen. Fishberg speaks of that form of diarrhœa which comes on late in pulmonary tuberculosis as almost invariably fatal and rapidly fatal. It is peculiarly disappointing to the practitioner treating pulmonary tuberculosis by artificial pneumothorax, when this diarrhœa, at first casual, then frequent but intermittent, and finally persistent, attacks a patient whose lung has been collapsed, apparently to a stage of complete arrest. Then may come this sequela, a rapid extinction of vitality, and then death.

I have sometimes wondered whether artificial pneumothorax has, in one or two cases out of a large number, produced this diarrhœa; but I have then remembered that it is so common a sequel where no such treatment has been tried that I have not been able to see cause and effect in the chain of occurrences. Treatment may be successful in slight cases, but may utterly fail, and I think it generally does where the enteritis is of vast extent. A recent French remedy is salicylate of alumina. I have only tried it in very advanced cases, and I am not frowning on its use when I say that in these very advanced cases it has done no good. Acetate of lead and opium, sulphate of copper and opium, and pulv. confect. arom. cum opio are all of value. Washing out the bowel with large enemata is advised by some, but may cause intense pain.

The remedy which I have found of the most value has been bismuth subcarb. in elephantine doses; I have given single doses of from ʒiv. to ℥ii. (In giving such a dose of bismuth subcarb. it must be guaranteed practically free from arsenic.) I have found no remedy to equal this. One large dose taken in milk, the patient drinking it slowly and taking, perhaps, two hours in swallowing one dose, has often cut short an attack of this distressing diarrhœa. It cannot be repeated for three days, but other remedies, especially pulv. confect. arom. cum opio, can be continued. I have known this treatment to be of great benefit in persistent mucous colitis. It is hypothetically possible that such a large dose of bismuth may produce intestinal obstruction. I have met with no such result.

I am, Sir, yours faithfully,
Leeds, Sept. 21st, 1925. H. DE CARLE WOODCOCK.

THE GEOGRAPHICAL DISTRIBUTION OF HEART DISEASE.

To the Editor of THE LANCET.

SIR,—The interesting map published in your last issue by Dr. Matthew Young recalls in a striking way the distribution in these islands of a number of other phenomena. I give as examples the yield of turnips per acre, the proportions of land occupied by cereal crops which are used for oats and wheat respectively, the distribution of the snails *Hygromia fusca* and *Theba cantiana*, and of the pearl-mussel *Margaritana margaritifera*, and lastly, the rainfall, which, though a commonplace, is often overlooked. Historians also remark that in the Civil War the country to the south and east of a line from Hull to Gloucester and Plymouth was for Parliament, and that to the north and west for Charles. The distinction between north-western and south-eastern is evidently of wide and varied biological significance, and its explanation is probably discoverable by careful statistical analysis, such as Dr. Young's, though the pitfalls in correlating variables are sufficiently illustrated by the examples I have given; it is unlikely that the parasite which causes acute rheumatism lives in the turnip, or that there is an anti-rheumatic emanation from *T. cantiana*. Taken in a broad way it seems much more likely that the dominating factors are dryness and what we may call civilisation. The actual rainfall in the south-east is much less, the calcareous strata of which it is largely composed are more permeable, a more intensive and thorough agriculture helps to keep the surface dry, which is, indeed, the effect of many modern improvements like street paving and tarred roads; there is much evidence that the south and east of England has become progressively drier during the last 100 years. Associated with this dryness in many such ways is a different standard of living. When Cæsar came to Britain he found culture at its highest level in the south-east, and, excepting, of course, Manchester, the same remains roughly true to-day; it may be because the south-east is nearer the Continent, or because its sunshine is more cheering than the rain of the north-west, or because, for a variety of reasons, it is more prosperous. But it is only necessary to travel across England from west to east, say from Hereford to London, and look out of the railway carriage window to appreciate that the conditions of life are not the same, and it is not difficult to believe that ugly (but waterproof) modern cottages and well-tilled clean fields may be better for the health of the inhabitants if they leave little "real country" for holiday-makers. These very brief indications show the inter-related complexity of the subject. Temperature seems to have relatively little influence; in winter the country is progressively cooler from west to east, and in summer from south to north, and there is no period at which the distribution of temperature corresponds for any length of time to the biological divisions.

"SMALARINA" IN MALARIA.

To the Editor of THE LANCET.

SIR,—In your issue of June 27th I read a brief clinical report by Dr. G. C. Low and Dr. A. L. Gregg on my method of malaria therapy with smalarina. There are, however, some slight mistakes in that note in connexion with the practical application of this method as reported, and these I should like to discuss. Dr. Low and Dr. Gregg, when treating their patients, had probably not read my papers and pamphlets or had forgotten the rules I suggested for carrying out the treatment. From their report I gather that:—

1. The patients, when the smalarina treatment was started, were feverish, that is, in an acute stage or in a state of relapse.

2. Smalarina was administered in order that the fever might abate at a fixed time.

3. Since the fever did not abate, quinine was given, and in a (relatively) short time this treatment established a rapid convalescence with the disappearance of the parasites from the peripheral blood-stream, of fever, and of splenic enlargement. These fortunate results were *attributed* to the administration of a few doses of quinine.

It is to be noted that no treatment with quinine alone was carried out as a control.

The points I wish to raise in regard to the above results are as follows:—

1. *In all my publications I have clearly maintained* that the new therapy is a "biological therapy," that is, it produces an organic reaction and immunity, and is by no means a pharmaceutical, symptomatic, febrifuge treatment. *Quinine will suffice to fight* the fever.

2. So far as smalarina treatment is concerned, it must be remembered that it is not suited for the acute stages of malaria because there the administration of quinine is necessary to reduce the fever. Smalarina tends to provoke an immunity against malaria.

3 The therapeutic action of smalarina manifests itself sometimes a little late. This action appears very *often* associated with a feverish reaction, which on analogical grounds I have named Herxheimer's reaction

4. One of the first symptoms in connexion with the reaction to the smalarina *stimulus* is the *rapid* diminution of the splenic enlargement.

5. It is consequently necessary, as I have already pointed out, that the after-care of the patients be continued sometimes for one or two months. During this time the characteristic symptoms of the disease are gradually disappearing and a general improvement in health becomes manifest.

Let us consider now the action of smalarina. Since this compound is not a febrifuge, it is hardly reasonable, for all practical purposes, to expect that the fever should abate after its administration. I have never maintained the febrifuge action of smalarina. Dr. Low and Dr. Gregg have done well in giving quinine in their cases, but quinine would have not been either advantageous or necessary in the subacute, chronic, masked, and latent malaria forms. Although no clinical control was carried out by using quinine alone, the rapid recovery which the patients made on the administration of quinine, and the rapid diminution of the splenic enlargement in the cases reported, should surely cause some surprise if that effect is attributed to the quinine. Either the recovery is a symptomatic one, manifested in the cessation of fever and the disappearance of the parasites from the peripheral blood-stream, but leaving the patient still infected with malaria, or it may be considered as sterilisation with a rapid improvement of the subject and rapid diminution or disappearance of the splenic enlargement. In the first alternative the quinine may really be the effective factor, in the other this drug may not play any part, but we may be dealing with the self-protective action of the tissues, as in recoveries which are spontaneous or are provoked by a biological stimulus. If Dr. Low and Dr. Gregg follow up their three patients they will discover that the splenic enlargement has entirely disappeared and that the fever will not recur. This result never occurs after such brief treatment with quinine. The whole malaria problem belies such optimism.

To obviate certain mistakes in such clinical experiments I should like to make the following points clear. When we treat a patient with smalarina, we must forget our ideas on the pharmaceutical therapy, particularly on the usual method of treatment. The practitioner usually takes note of the most evident symptom, the fever, which indeed does not represent the disease (nor when it disappears has the disease been eradicated), but he does not take note of the deep-seated constitutional lesion which is produced by an hereditary defect. The new biological therapy produces an organic reaction occurring at various times according to the organism in question. It represents, therefore, a result of a natural law and arises when Nature wishes. If we treat a patient with the new method and expect some determined results at a fixed time, that means we claim that our law is superior to natural law.

By limiting himself to observation of results the malariologist will not only see his patient's recovery but also a series of very interesting and unexpected phenomena, as did those colleagues who have obtained fortunate results by following the method according to the rules that I have suggested. Treatment will not be successful if carried out under wrong conditions. The bad results, however, that we obtain in these cases appear to be only transitory, and the proof of this lies in the fact that we clearly see the advantages of the new method when we follow up the patients for some time after treatment. Chemical therapy, as rapid as it is ephemeral, has made us accustomed to expect some prompt results, and when these are not forthcoming we say the therapy has failed. If, however, a therapeutic method can produce an organic reaction (feverish reaction) after 10–15 days of treatment and a sterilisation after one or two months, it is evident we are dealing with something which is not a "pharmaceutical" treatment. Until we have thoroughly and at length experimented with this "something," we cannot say it has failed to produce the desired results.

The cases and method of application of Dr. Low and Dr. Gregg do not conform to the postulates I have established—namely, a rigorous application of some therapeutic rules that I have published after many years of diligent research.

I am, Sir, yours faithfully,

Rome. GUIDO CREMONESE.

JOURNALS FOR MEDICAL MISSIONARIES.

To the Editor of THE LANCET.

SIR,—May I, through your columns, make known the need of medical literature for members of the medical profession who work in hospitals scattered over the world? I have at the moment three requests for THE LANCET, and would gladly supply addresses to which such literature should be sent regularly.

I am, Sir, yours faithfully,

JANET BRADBURY,
S.P.G. Sec. for Medical Literature.

Darenth House, Sandgate, Kent, Sept. 19th, 1925.

MACLEAN'S "LAG" BLOOD-SUGAR CURVE.

To the Editor of THE LANCET.

SIR,—MacLean has specially called attention to a peculiar disturbance of blood-sugar regulation characterised by what he calls the "lag" blood-sugar curve.[1] By this name he denotes a condition in which, when a sugar-tolerance test is performed in the way he describes,[2] blood-sugar rises above the normal threshold value of about 0·18 per cent. within half an hour after the ingestion of sugar, but goes down again very quickly and is quite normal within two hours (or, in the old, within three hours) after the ingestion of sugar. A more or less important glycosuria is also produced.

A point of great practical importance is the prognostical significance of this type of blood-sugar curve. For the present, MacLean takes the view that "a patient who gives this lag type of curve, but *who shows no delay in the return of blood-sugar to normal after ingesting sugar*, is probably not suffering from a defect which is likely to prove prejudicial to his carbohydrate metabolism."

I have recently seen a case which has, I believe, some interest from this prognostical point of view.

J. M., aged 66. Thirty-six years ago sugar was found in the urine. A slight food restriction banished the glycosuria, which was constantly found absent so long as the food restriction was maintained. A few years later both food restriction and urine examinations were discontinued until 1918, when a urine analysis was again performed and sugar was found. Since then the analyses have been frequently repeated and glycosuria has always been found, varying from traces up to 3·0 per cent. Changes in glycosuria have been found to correspond with those in the diet. Food restriction was never very serious, bread and potatoes, for instance, being never omitted. No diabetic symptoms were noticed at any time. The patient has always felt very well and vigorous. At present he is an exceedingly healthy-looking old gentleman, is not, and has never been, over weight, and his blood pressure is 120/75.

A blood-sugar tolerance test, with 50 g. sugar, performed on Sept. 2nd, 1925, gave the following figures:—

	Blood-sugar per cent.		Urine sugar per cent.
Fasting	0·11	....	Nil
30 minutes after ingesting sugar	0·205	....	—
2½ hours " " "	0·10	....	1·3

The main interest of this case lies in the fact that a blood-sugar regulation disturbance of the "lag" curve type has existed for at least 36 years, neither being the cause of any clinical disturbance except glycosuria, nor showing any tendency to pass into a true diabetes, despite the fact that no serious diet has ever been kept and that, probably, glycosuria has constantly been present, except for a short number of years after it was first discovered. This

case is therefore strongly in favour of MacLean's optimistic opinion on the prognostic significance of the "lag" blood-sugar curve. It is also of interest to remark that in this case of non-diabetic dextrosuria, as, probably in all those of the same type, changes in diet are followed by changes in the daily excretion of sugar of the same type as those met with in true diabetes, in opposition to what is seen in typical renal glycosuria and other non-diabetical glycosurias. This fact emphasises the importance of performing sugar-tolerance tests, with blood-sugar determinations, in all cases of glycosuria in which the diabetic nature of this symptom is not quite evident, even when it may seem possible to exclude renal glycosuria and other non-diabetic glycosurias, such as lævulosuria, pseudo-lævulosuria, &c.

LUMINAL IN EPILEPSY.

To the Editor of The Lancet.

Sir,—I have read, with great interest, the letter of Dr. Hildred Carlill in The Lancet of Sept. 19th on a case of luminal poisoning. For the last three years I have had the opportunity of studying the action of luminal and I have found that, except in cases of epilepsy, in which cases the number of fits was reduced very considerably, the drug was very disappointing. The dose we give here is 2 gr. twice daily. Larger doses when tried as a sedative or hypnotic have not given satisfactory results, in fact very disappointing, as the patient becomes stuporous, restless, and in a few cases the sphincters were relaxed. Gradual decrease in the dose of luminal is essential, but a sudden cessation may cause the same symptoms as a large dose.

I am, Sir, yours faithfully,
S. Grossman,
Assistant Medical Officer, Cardiff City Mental Hospital.

Sept. 22nd, 1925.

Medical News.

Fellowship of Medicine and Post-Graduate Medical Association.—The Fellowship of Medicine will hold a series of lectures on Tuberculosis in the Lecture-room of the Medical Society, 11, Chandos-street, in October. The opening lecture will be delivered on Oct. 12th at 5.30 P.M. by Dr. L. S. Burrell on Tuberculosis *from the Physician's* Viewpoint. There is no fee for this series, and all members of the medical profession will be welcomed. During October there will also be held the *following* courses: Diseases of the Throat, Nose, and Ear at the Central London Throat, Nose and Ear Hospital (an *operative surgery class* will also be held); a course in Tropical Medicine, consisting of eight clinical demonstrations on Tuesdays and Thursdays; a combined course in Diseases of Children at the Paddington Green Hospital, Victoria Hospital, and Children's Clinic; a course in Urology at St. Peter's; and a course in Dermatology at St. John's. Copies of any syllabus, together with the Fellowship programme, may be obtained from the Secretary, at 1, Wimpole-street, W. 1.

Charing Cross Hospital Medical School.—The distribution of prizes to students by Sir Herbert Waterhouse will be made in the out-patients' hall of the hospital on Monday, Oct. 5th, at 3.30 P.M.

University of London: University College.—On Monday, Oct. 5th, and Tuesday, Oct. 6th, 10 A.M. to 1 P.M., first-year students of the Faculty of Medical Sciences will be received by the Senior Tutor, the Dean of the Faculty, and the Sub Dean. On Monday, Oct. 5th, 2.15 to 4 P.M., students of the Faculty of Medical Sciences other than first-year will be received; on the same day at 3.15 P.M. candidates *for the* Diploma of Public Health will be received by Mr. Delafield, Acting Head of the Department. The new buildings for anatomy, anthropology, embryology, histology, and physiology, provided by the gift of the Rockefeller Foundation of New York, are now in full use. The list of public lectures includes six on the Study of Man by Prof. G. Elliot Smith and Dr. C. F. Sonntag, and one on the Photochemistry of Vision by Prof. Fritz Weigert *of the* University of Leipzig. There will also be eight lectures on the Physiology of Hearing and Vision, which will be given by Mr. R. J. Lythgoe on Mondays and Wednesdays at 5 P.M., starting on Oct. 12th.

Lectures at King's College.—A course of ten lectures on the Histology of Nerve Tissues and Paths of Conduction in the Central Nervous System will be given by *Dr. C. Da Fano* at King's College, at 5 P.M., on Thursdays during the present session, beginning on Oct. 8th.

The People's League of Health has awarded a travelling scholarship to Miss Alice Gilby, who is a second-year medical student at the London School of Medicine for Women.

At the third annual general meeting of the British Provident Association for Hospital and Additional Services, held on Sept. 21st, a resolution was passed expressing the Association's appreciation of the services of the late Dr. J. F. Gordon Dill in the cause of the voluntary hospitals of this country.

Imperial Social Hygiene Congress.—The British Social Hygiene Council, which was lately the National Council for Combating Venereal Diseases, is organising a congress to be held at Wembley from Oct. 5th *to* 7th under the presidency of Sir Auckland Geddes. Distinguished representatives of the Dominions have agreed to take part in the discussions, and addresses will be given by Mr. L. S. Amery (*Colonial Secretary*), Mr. Neville Chamberlain (Minister of Health), and Lord Willingdon. The problem of venereal disease as it affects the *Empire* will be fully discussed.

Cork Dental Hospital.—The honorary staff of this hospital, which forms part of the North Infirmary, have resigned in a body on a number of grounds. The staff complain, generally, that the committee of management have "persistently ignored" their recommendations, even upon matters regarding which they are especially *qualified* to advise, and, more specifically, that they were not consulted upon the opening of the hospital at night, and that two salaried appointments were recently made in face of their opposition. The honorary staff has been invited to a conference with the committee of management *and* has been asked to continue duty in the meantime.

London Medical Exhibition.—From Oct. 5th to 9th the medical profession will again have an opportunity to taste, see, or handle the products of our leading drug houses and scientific manufacturing firms at the Central Hall, Westminster, S.W. The London Medical Exhibition, which is open to medical men only, will comprise the most recent organo-therapeutic, bacteriological, and pharmaceutical remedies and prophylactics; electro-therapeutic apparatus; scientific dietary; surgical instruments; hospital furniture and medical appliances, diagnostic material, and apparatus; pathological and physiological apparatus; artificial limbs, aids in invalidity *and deformity*; sick-room requisites; natural and artificial hydrotherapy; professional literature; hygienic clothing, and *so forth*. Invitation cards can be obtained from the secretary of the exhibition, 194–200, Bishopsgate, London, E.C., *or* at the Central Hall during the exhibition. The exhibition is exclusively for members of the medical profession.

Donations and Bequests.—By the will of the late Mrs. Catherine Ada Potter, of Llandaff, the testatrix left £1000 to Cardiff Royal Infirmary "to *endow* a bed in a ward to be called the Catherine Ward," and £100 in addition "on condition my grave is kept in good order and looked after by such infirmary." Among other bequests she left £100 to the Cardiff Blind Institution.—The Manchester Royal Infirmary has received £10,000 on account from a legacy by the late Miss Ann Russell.—Mrs. Ellen Margaret Smith, Aughton, Lancashire, who left £12,911, besides other bequests, including certain sums to her husband, left on his death £500 each to the School for Indigent Blind, Liverpool, the Hospital for Women, Liverpool, and the Ormskirk District Nursing Association.—The Christie Hospital, Manchester, has received a donation of £1000 from Mrs. Taylor, of Whalley Range, to endow a bed in memory of her husband and brother-in-law, Mr. Henry Marsland Taylor and Mr. James Henry Taylor, two of Manchester's oldest solicitors.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Thursday, Oct. 1st:

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.

Specimens:

Mr. Beckwith Whitehouse: (1) Endometrioma invading Bladder, from a patient who had never menstruated. (2) Intra-ligamentary Endometrioma.

Short Communications:

Mr. A. C. Palmer: Acute Purulent Salpingitis at the Third Month of Pregnancy.

Dr. A. P. Thomson and Dr. Lamb: Malignant Endometrioma with Metastases in the Lungs.

Paper:

Dr. I. C. Rubin, of New York (introduced by Mr. Clifford White): Diagnostic Value and Therapeutic Application of per-Uterine Insufflation of the Fallopian Tubes in Cases of Sterility.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.

MONDAY, Sept. 28th, to SATURDAY, Oct. 3rd.—WESTMINSTER HOSPITAL, Special Post-graduate Course in General Medicine and Surgery, and the Special Departments. 10.30 to 5.30 daily. Demonstrations, lectures, &c. Second week.—HOSPITAL FOR CONSUMPTION AND DISEASES OF CHEST, Brompton. Post-graduate Course in Diseases of the Chest. Operations, lectures, lecture-demonstrations, demonstrations of surgical cases, of cases in wards, and in special departments. Second week.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Lecture-demonstration on Treatment by Electrotherapy on Wed., Sept. 30th, and the two succeeding Wednesdays at 5.30 P.M., by Dr. C. B. Heald: The Diathermy Current—Its Uses and Application.

OPENING OF LONDON MEDICAL SCHOOLS.

TUESDAY, Sept. 29th.—GUY'S HOSPITAL. Address by Major Ian Hay Beith (Ian Hay).

THURSDAY, Oct. 1st.—ST. BARTHOLOMEW'S HOSPITAL. Old Students' Annual Dinner in Great Hall of Hospital. Chairman: Mr. J. Adams.—CHARING CROSS HOSPITAL. Annual Dinner.—ST. GEORGE'S HOSPITAL. School Dinner at Hyde Park Hotel. Chairman: Dr. Ashton Warner.—KING'S COLLEGE HOSPITAL. 2.30 P.M., Introductory Address by Sir Arthur Keith. 7 P.M., Annual Dinner of Past and Present Students at Connaught Rooms, Great Queen-street.—LONDON HOSPITAL. Annual Old Students' Dinner, Trocadero Restaurant, Piccadilly Circus.—MIDDLESEX HOSPITAL. 3 P.M., Prize Distribution in Queen's Hall by Hon. Sir Arthur Lawley; Inaugural Address by Dr. C. E. Lakin on Tradition in Medicine. Annual Dinner, New Criterion Restaurant, Regent-street. Chairman: Sir Arnold Lawson.—WESTMINSTER HOSPITAL. 3 P.M., Inaugural Address by Prof. A. E. Gardner in Board Room of Hospital.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Sept. 29th.—4.15 P.M., Mr. H. H. Rayner: A Survey of the Treatment of Duodenal Ulcer.

FRIDAY, Oct. 2nd.—4.15 P.M., Dr. E. M. Brockbank: High Blood Pressure as a Cause of Disablement in Workers.

Appointments.

DOW, D. R., M.D., Ch.B. St. And., D.P.H., has been appointed to the Chair of Anatomy, University College, Dundee.

GIRI, D. V., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., .O. Oxf., Honorary Surgeon to the Royal Eye Hospital, Eastbourne.

HEWAT, A. F., M.B., Ch.B. Edin., F.R.C.P. Edin., Acting Physician to the Chalmers Hospital.

MUIRHEAD, JANET L. A., M.B., Ch.B. St. And., Tuberculosis Officer for the Burgh of Arbroath.

WOLFENDEN, H. F., M.D., F.R.C.S., Honorary Surgeon, Royal Infirmary, Liverpool.

Queen Charlotte's Maternity Hospital: LANKESTER, A. L., M.R.C.S., L.R.C.P. Lond., Senior Resident Medical Officer, and NELKEN, G. J. V., B.S. Lond., Assistant Resident Medical Officer.

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal United Hospital.—H.P. £125.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.S. and Asst. H.P. Each at rate of £100. Also Asst. S. 50 guineas.

Birmingham General Hospital.—Asst. S. £50.

Chelsea Hospital for Women, Arthur-street, Chelsea, S.W.—S.

Colchester, Essex County Hospital.—Radiologist.

Delhi, India, Lady Hardinge Medical College and Hospital.—Radiologist. Rs.750.

Eastern Dispensary, Leman-street, E.—P. £65.

Hackney Hospital, 230, High-street, Homerton, E.—Jun. Asst. M.O.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Res. M.O. and H.P. At rate of £150 and £100 respectively.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each at rate of £50.

King's College Hospital, Denmark-hill, S.E.—Clin. Assts. Med. and Surg. Out-patient Officers, &c.

Lucknow University.—Prof. of Surgery. Rs.1200–50–1400.

Manchester, Ancoats Hospital.—Asst. Surg. Reg. £40.

Manchester Babies Hospital, Burnage-lane, Levenshulme.—Res. M.O. At rate of £125. Also Clin. Asst. At rate of £50.

Manchester Royal Infirmary.—Res. M.O. and Asst. M.O. At rate of £200 and £100 respectively.

Mental Hospitals Service under the L.C.C.—Eighth Asst. M.O. £432.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Asst. Cas. O. At rate of £100.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Pathologist. £500.

Norfolk County Council.—Asst. Tub. O. £600.

Norwich City.—Temp. Asst. Sch. M.O. £11 11s. weekly.

Paddington Green Children's Hospital, W.—H.P. and H.S. Each at rate of £150.

Royal Chest Hospital, City-road, E.C.—Res. M.O. and H.P. At rate of £150 and £100 respectively.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Registrar. £100 guineas.

Royal Northern Hospital, Holloway, N.—P.

St. Luke's Hospital, Chelsea, S.W.—Third Asst. M.O. £325.

St. Pancras Metropolitan Borough.—Asst. M.O. £600.

Salford Royal Hospital.—Radiologist. £300. Also Med. Reg. £250.

South Shields County Borough.—Ven. Diseases M.O. £750.

South Shields, Ingham Infirmary.—Jun. H.S. £150.

Throat Hospital, Golden-square, W.—Two H.S.'s. At rate of £100. Also Hon. Surg. Reg.

Torquay, Torbay Hospital.—Res. M.O. £200.

Whipps Cross Hospital, Leytonstone.—Specialist Consultant in Light Treatment. £300.

Willesden Urban District Council.—Two M.O.'s. Each £600.

York City Mental Hospital, Fulford, York.—Asst. M.O. £440.

Births, Marriages, and Deaths.

BIRTHS.

BUCHANAN.—On Sept. 13th, at a nursing home, the wife of John V. Buchanan, M.B., Ch.B., Dale House, Shaw, Lancs, of a daughter.

COLLINS.—On Sept. 11th, at Garden Reach, Buckhurst Hill, the wife of Dr. F. Garland Collins, of a daughter.

LYNHAM.—On Sept. 10th, the wife of Dr. J. E. A. Lynham, of The Moorings, Matham-road, East Molesey, of a son.

MARRIAGES.

DUGUID—BENZIE.—On Sept. 17th, at King's College Chapel, Old Aberdeen, John Bright Duguid, M.D., Lecturer on Morbid Anatomy, Manchester University, to Agnes Mildred Emslie, M.B., Ch.B., D.P.H., elder daughter of Mr. and Mrs. A. Emslie Benzie, of Morkeu, Cults, Aberdeenshire.

DEATHS.

GATLEY.—On Sept. 20th, at Surbiton-road, Kingston-on-Thames, Henry Ralph Gatley, M.R.C.S., aged 67.

KIRKNESS.—On Sept. 19th, at The Haven, Pembury, Tunbridge Wells, suddenly, of pneumonia following influenza, William Ronald Kirkness, M.R.C.S., L.R.C.P.

RUSSELL.—On Sept. 20th, at Haytor, Devonshire, James W. Russell, M.A., M.D., F.R.C.P., of Chad-road, Edgbaston, Birmingham, in his 63rd year.

RYAN.—On Sept. 18th, at The Laurels, Crumlin, Mon., Edmond Ryan, M.D.

SALAMAN.—On Sept. 19th, at Bayswater-terrace, London, Colonel S. M. Salaman (I.M.S., retd.), aged 81 years.

STEELE.—On Sept. 15th, Henry Francis Arthur Steele, M.R.C.S., aged 75.

WEBB.—On Sept. 13th, at Haverstock-hill, Vere George Webb, M.R.C.P.I., aged 73.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

SELECTION OF COD-LIVER OILS FOR MEDICINAL USE.[1]

By J. C. Drummond, D.Sc., F.I.C.,
PROFESSOR OF BIOCHEMISTRY, UNIVERSITY COLLEGE, LONDON.

It is almost generally accepted at the present time that the beneficial influence exerted by cod-liver oil on certain conditions of malnutrition is due largely to the presence in relatively high concentrations of at least two organic substances provisionally classed as vitamins. Older theories that ascribed the action to the peculiar nature of the unsaturated fatty acids in fish liver oils, or to the traces of iodine which they frequently contain, have been disproven by the demonstration that the material which resists saponification when the oils are treated with an alcoholic solution of caustic alkalies, and which can then be separated by extraction of the soap solution by suitable solvents, contains all the active substances. Such material from the method of its preparation can contain no unsaturated fatty acids, nor is it found to contain even minute traces of iodine.

Source of Vitamins in Cod-liver Oil.

In collaboration with Dr. Zilva, of the Lister Institute of Preventive Medicine, the writer has for a number of years past carried out an exhaustive series of researches to ascertain the source of the vitamins in cod-liver oil, and the cause of the variations which occur in the amount present. The result of these studies is not without some practical interest to the medical practitioner, because quite a number of views seem to be still widely held that have been found by us to have no foundation in fact.

In the first place may be mentioned the old idea that the almost black or dark brown oils prepared by the now almost obsolete process of "rotting" the livers were much more valuable than the clear white oils that are generally sold to-day. For this view we found not the slightest experimental support; indeed, we were inclined to believe that the exposure of the "rotting" oils in vats to the open air and sunshine for considerable periods tended to decrease their vitamin content by causing oxidation.

The introduction of the modern method of steaming the absolutely fresh livers and thereby obtaining a clear white oil rapidly brought about the disappearance of the dark brown oils as medicinal agents, and led to a demand for higher grade products. Although the "steaming" process appears first to have been used by an Englishman, Charles Fox, as early as 1848 in Newfoundland, its widespread adoption is probably due more to the labours of Peter Möller in Norway during the second half of last century. He operated factories in the neighbourhood of the Lofoten Islands, and a few years after the introduction of the improved method of extraction Norway was producing clear white oils of a much higher grade of quality than formerly. The Norwegian industry, largely centred at that time in the Lofoten Islands, when putting their oils on the market made a strong point of the fact that only livers of the cod were used, and that the oils were extracted from the livers removed from the fish very shortly after they were caught. From this has grown the idea, still widely held especially in trade circles, that only oils from the liver of the cod are of medicinal value, and that Lofoten oils are the best that can be obtained.

"Pure" Cod-liver Oil.

At an early stage in our researches Dr. Zilva and I found that the oils yielded on steaming the livers of other gadoid fish—pollock, haddock, ling, coalfish, &c.—are quite as rich in vitamins as that from the cod's liver. There is, therefore, no justification for demanding that an oil to be used for therapeutic purposes should be a "pure" cod-liver oil. In some cases to make such a demand is to run the risk that a product of rather low vitamin value may be obtained, because, as we have fully described elsewhere, in Norwegian waters "pure" cod-liver oil is only made in the Lofoten and Romsdal areas early in the year when this species is spawning on the shallow sandy banks—a period in the life of the fish when there tends to be a transference of vitamins from the liver to the gonads. There seems to be no doubt from our investigations on the fishing grounds in Norway, Newfoundland, and the North Sea that the chief factor governing the amount of vitamin in the liver of the gadoid fish is their food-supply. When the fish are actively feeding their livers are usually rich in vitamins and yield clear, pale yellow oils of very high medicinal value; on the other hand, when they are practically starving during the spawning period, and are at the same time transferring much fat and vitamin to the reproductive cells, the livers yield an almost white oil of relatively low potency.

It cannot be too strongly emphasised that it is not undesirable that oils should possess a pale lemon-yellow colour. On the other hand, it has been my experience to find that such oils usually possess a higher medicinal value than "white" oils. Only dirty yellow and brown oils, indicating unsatisfactory preparation, are undesirable.

Of the oils derived from Norway, therefore, we have usually found those from the Finmarken coast, where the fishing is carried on from June to August, while huge shoals of mixed gadoid fish pass slowly along the northern coast of Norway feeding actively on smaller species, mainly the caplin (*Mallotus villosus*), to possess the highest vitamin value. Generally speaking, they are found to be from five to ten times more valuable than the average oil prepared in the Lofoten area, although wide variations may occasionally be encountered.

High Value of Newfoundland Oils.

It is of considerable interest in the light of these observations to point out the value of the oils prepared in the Dominion of Newfoundland. Until recently the sale of oils from this source for medicinal purposes was relatively small, and they were practically ousted from the market by the strong preference for Norwegian, especially Lofoten, oils. Dr. Zilva and I ascertained, however, that the Newfoundland oils possess a very high average value as sources of vitamins, and an investigation carried out on the fishing grounds there enabled us to understand why this is so. The main fishing season, during which over two-thirds of the entire annual catch are taken, is in the summer months when the fish are off the east coast of the island, the remainder being caught in spring and winter in the Gulf of St. Lawrence, the Straits of Belle Isle, or off the Labrador coast. During the whole of the main fishing season the fish are actively feeding, early in the summer on the caplin, later on squid and herring. The oils made during this period are, therefore, found to be of high vitamin value, and comparable with the oils made in summer in the Finmarken area of Norway, with the exception that the Newfoundland oils are prepared practically entirely from cod.

Compared with Norwegian oils the proportion made during periods when the fish are spawning is very small in Newfoundland, and it is to this that Dr. Zilva and I are inclined to ascribe the high average value of the Dominion products.

Quality of the Oil from the Trade Aspect.

There remains, however, one important question that is frequently raised when the superior nutritive value of the oils from our oldest colony is emphasised—namely, the quality of the oil as viewed from the trade aspect. In the past the Norwegians have undoubtedly captured the market by the obvious superiority of their products. Their oils have been clear, free from marked coloration, and more particularly from the unpalatable characteristics of oils prepared from old livers or by unsatisfactory processes. To a large extent this superiority was the cause of the strong prejudice against oils other than Norwegian which still survives, but matters are very different at the present time. In 1916, by an Act of the Newfoundland Legislature, the production of all cod-liver oil in the Dominion was put under the control of the Ministry of Marine and Fisheries. Every manufacturer is now required to hold a Government licence, to conduct his preparation according to certain rules laid down to ensure cleanliness, &c., and to permit his factory to be open to Government inspection and supervision. Great care is now taken by manufacturers to comply with the regulations, to see that no discoloured or stale livers are placed in the vats, to remove the gall-bladders, to maintain strict cleanliness of utensils, and in all ways to produce a product of high technical and market quality. A fuller description of the actual process, as now being worked in the Dominion, is given in our report in the *Journal of the Society of Chemical Industry* (1923, lii., 185 T and 250 T).

There should no longer be any prejudice against oils from Newfoundland, and it is fully time that medical men realise that we have within the Empire a source of medicinal cod-liver oil of very high quality in every sense. It may here be remarked that an American group of scientists visited Newfoundland shortly after our investigation had been made and confirmed our conclusions in all essentials. An immediate result of this has been that a number of the chief firms in the United States interested in cod-liver oil, or preparations containing this oil, have decided to erect their own factories in Newfoundland or to employ only oil from that source.

I am indebted to Major Victor Gordon, the High Commissioner for the Dominion of Newfoundland, and to Mr. W. A. Munn for the following figures representing the annual production since 1913. If they be compared with the figures representing the Norwegian output, for which I am indebted to H.B.M. Consul at Bergen, it will be seen that there is generally an inverse relationship. This opens up an economic question which it is inappropriate to discuss here, but it is certain that Newfoundland could supply much larger quantities of oil for medicinal use in this country if its uniformly high nutritive value were sufficiently appreciated by the medical profession and the public.

---

[1] This communication was written at our request, as it was found that information concerning Newfoundland cod-liver oil was needed by the medical profession.—Ed. L.

Comparison of Production of Medicinal Cod-liver Oil in the Dominion of Newfoundland with the Export from Norway for the Years 1913–24.

Oils Prepared in Great Britain.

In conclusion, brief mention should be made of the oils prepared in this country. Until quite recently the amount of medicinal oil prepared from fish landed at ports in Great Britain was negligible, the livers usually being thrown away or landed in a state of decomposition so advanced as to render them unfit for the manufacture of any form of oil other than commercial "cod oil," a technical product used mainly in the leather industry or for conversion into soap. Within the last year or two certain manufacturers have made arrangements for steaming the fresh livers on board the trawlers at sea, and an appreciable quantity of oil of quite good market quality is now being made for medicinal use. As far as Dr. Zilva and I could determine the average vitamin value of these oils is fairly high, but we have not had the opportunity of making so extensive an examination as we had in Norway and Newfoundland. The fish are caught over a wide area, extending beyond the North Sea to the Faröe Islands, Iceland, and even as far as the White Sea. Probably no great proportion of spawning fish are present in the catch, even in the early months of the year, but we have no definite information on this point. It is certain, from a considerable number of samples that we have examined, that cod-liver oils of good trade quality and high medicinal value can be placed on the market by manufacturers in this country if they are prepared to go to the trouble of working up the livers immediately after the fish are caught. Usually this means the installation of steaming plants, which, however, may be of very simple construction on the trawlers, as the majority of the boats are away from port for periods of from one to six weeks.

PUBLIC HEALTH IN BOMBAY.

THE population of Bombay at the 1921 census numbered 1,175,914, and at the middle of 1923 was estimated at 1,220,120, on which latter figure the birth and death ratios have been calculated. The birth-rate was 17·20 per 1000; or, if calculated on the census population, the ratio would be 17·85. In that year the birth ratio for the Presidency, as a whole, was 33, and for the city 16. The explanation of this low ratio is stated by Dr. J. E. Sandilands, Executive Health Officer, who presents this report, to be due partly to the custom whereby married women leave the city for their confinement, and so register their children in the mofussil districts where they are born, and partly because some births in the city are not registered. 1487 births were inquired into in 1922 and 1923, and it was found that 68 per cent. only of these infants were born in Bombay, [illegible] having been born elsewhere; and, out of 8632 [illegible] during the year, 31 per cent. occurred in [illegible] "Of the [illegible] born outside [illegible] more be [illegible] where"; [illegible] be

JANET L. A[illegible] the Burgh [illegible] E., M.D., one-third [illegible] erpool. registered, [illegible] Maternity 100. Th[illegible] 1000

Lingaits is obviously due to an understatement of the Lingait population in the census returns." The registered births numbered 146, and the deaths 339; the Lingait population is stated to be 866. Disregarding this group, the death-rate varied from 8·81 among Banias, and 11·45 among Europeans, to 29·24 for Hindus of all castes, 32·10 for Indian Christians, 34·23 in Jains, 34·89 in Anglo-Indians, and 43·73 in Mussulmans. Jains suffered most heavily from plague (2·75 deaths per 1000), the general plague mortality being only 1·08 per 1000; for Hindus of all castes 1·20, and for Europeans 0·13. "The liability to plague is not improbably due to the fact that Jains do nothing to prevent rats entering and living in their houses." Enteric fever was most fatal to the Parsees (0·64), Bhatias (0·53), and Europeans (0·45), the general enteric mortality being only 0·11 per 1000.

Mortality from All Causes.

In regard to the mortality from all causes in the different wards and sections of the city, the ratios varied from 16·56 per 1000 (Fort South section of Ward A), and 10·05 (Walkeshwar in Ward D), to 36·90 in Worli section (Ward G), and 42·06 in 2nd Nagpada section (Ward E). The infantile mortality varied from 236 per 1000 births in 1st Nagpada section of Ward E, and 264 in Walkeshwar section (Ward D), to 521 in 2nd Nagpada (Ward E), also in Mandvi (Ward B), 534 in Sion section (Ward F), and 548 in Byculla (Ward E). As the registration of births is faulty, the infantile deaths in relation to the *total population* at all ages are separately stated. This ratio varied from 1·86 per 1000 in Fort South (Ward A) to 9·77 in Byculla section (Ward E), and was 7·07 for the city as a whole. The excessive mortality is largely due to overcrowding; 14,302 births (68 per cent. of the total) took place in families living in a single room or sharing it with others, the infantile mortality being 524·1 per 1000 births. In families occupying two rooms the mortality was 394·5; in three rooms, 255·4; in four or more rooms, 246·5; in hospitals, only 112·2. Much work has been done to remedy this deplorable state of things by visits of nurses, attendance on confinements, provision of necessaries, of maternity homes, milk depôts, and infant welfare centres. The municipal nurses paid 54,102 visits, and attended 1014 confinements. Besides this 1773 cases were admitted to the municipal maternity homes; two infant milk depôts have been established, and the Maternity and Child Welfare Scheme of the Infant Welfare Society has made much progress.

Infectious Diseases.

The notifications of infectious diseases numbered 4575, of which total 1501 were for plague, 1274 for tuberculosis, and 978 for small-pox. Plague was epidemic from Feb. 17th to June 2nd, and caused 1320 deaths (1·08 per 1000 population, as compared with 0·67, the quinquennial average). Of these 1202 occurred within the dates mentioned. The case mortality was 89 per cent. No fatal cases occurred in 1st Nagpada section of E Ward, and only one in Upper Colaba. All the other sections suffered more or less, most deaths occurring in Worli (251) and Mahim (172) sections (both in G Ward); and the highest mortality ratios falling on Mahim (3·31), Mahalakshmi (2·[illegible]2), and Worli (1·98 per 1000). The usual preventive and precautionary measures were continued during the year; infected dwellings were evacuated and disinfected, and temporary health camps established; 15,749 inoculations were performed; 725,574 rats destroyed, of which 305,283 were examined at the Parel laboratory, 2·77 per cent. being found to be infected. The percentage of infection rose from 1·63 in January and 3·55 in February to 6·75 and 7·42 in March and April. It then declined to 2·10 in June and 1·27 in July, and was below 1·0 per cent. for the rest of the year.

Small-pox was prevalent throughout the year, 978 cases being registered, of which 470 were fatal, compared with 130 cases and 61 deaths in 1922. The mortality ratio was 0·39 per 1000, as compared with 0·48, the quinquennial average. No fatal cases occurred in Upper Colaba. In the other sections the mortality was below 1·0 per 1000 in all except 1·04 in Fanaswadi (C Ward) and 1·21 in Chowpati (D Ward). The total primary vaccinations performed numbered 20,293, of which 97·65 per cent. were known to be successful. In addition, 21,725 persons were re-vaccinated. Of the 87 infants under 1 year of age who died from small-pox, 65 were not vaccinated, and one was vaccinated during the vaccinal incubation period. In the remaining cases the condition was not ascertained, a most regrettable omission.

Cholera was much more prevalent in the city than in the previous year. There were 323 attacks and 189 deaths, as compared with 22 and 15 in 1922; 41 of the cases were imported. No fatal cases occurred in Upper Colaba, Fort South, 2nd Nagpada, 1st Nagpada, or Sion sections. In the remainder, 30 deaths occurred in Market section, and in the adjoining Dhobi Talao, giving death ratios of [illegible] and 1·00 per 1000 respectively. There were two out[illegible] The first (June 6th to 27th) occurred among the [illegible]n pilgrims, coming from distant provinces and proceeding to Mecca; 16,961 passed through Bombay. They were accommodated as far as possible in three "Mussaferkhanas"; but as these buildings could not hold as many as 3000, many pilgrims had to be lodged in hired buildings with inadequate sanitary arrangements, or were encamped on the open spaces outside the Mussaferkhanas. Two cholera cases occurred in pilgrims arriving from infected provinces. During the month there were 25 attacks and 17 deaths. Sanitary measures were carried out, and 5065 pilgrims were inoculated with anticholera "vaccine"; the spread of the disease was checked. The second outbreak occurred among the city residents. There were 274 attacks and 155 deaths between July 16th and the end of August. The disease had prevailed in Poona, Ahmednagar, and other parts of the province, and "ample opportunities existed for the introduction of infection from the outside." Chlorination of the water-supplies was carried out, and inoculation stations opened, where 1710 persons were treated.

Influenza was registered as causing only 250 deaths (0·20 per 1000), as compared with 1·77 per 1000, the quinquennial average; but respiratory diseases, to which influenza deaths are frequently attributed, caused 14,099 deaths, as compared with 13,614 in the previous year. Tuberculosis caused 1871 deaths (1·12 per 1000), a satisfactory continuation of the improvement during recent years. In the decennium 1913-22, the mortality had averaged 1·95, and in 1922 it was 1·22 per 1000. The work carried on by the King George V. Antituberculosis League was taken over by the municipality in July. There are two dispensaries in the city, and a sanatorium with 82 beds on Bhoiwada Hill, Parel, known as the Turner Sanatorium; 1129 cases were treated at the dispensaries, and the medical officers visited 1258 patients too ill to attend personally.

Malaria was registered as the cause of 403 deaths, the diagnosis being verified in each case. In addition 2602 deaths were returned as due to "Ague and Remittent Fevers"; many of these may have been due to typhoid, tuberculosis, or influenza, in which fever may be a prominent symptom. Spleen examinations (10,553) were carried out among children in all of the 31 sections of the city except four (Kamatipura, Parel, Sewri, and Mahim). No splenic enlargement was found among 126 children in Fanaswadi section of Ward C. The total cases of enlargement numbered 930 out of 10,553 children examined, the ratios varying from 1·2 per cent. in Kumbharwada and 1·4 in Bhuleshwar (both in Ward C), to 10·67 in Tarwadi (Ward E), 10·80 in Fort South (Ward A), 18·7 in Sion (Ward F), 14·88 in Fort North, and 10·83 in Colaba (Ward A). It is regrettable to find that, in the report of the municipal laboratory, out of 1267 milk samples analysed 41·3 per cent. were adulterated. In Ward F the ratio was 62·9, and in Ward G 70·6 per cent.

AN UNUSUAL CAREER.

INFANT prodigies are always interesting in their infancy, but very few of them remain at all noteworthy in their later years. William Robert Grossmith, the son of a Reading picture-frame maker, was something of an exception to this rule. After an astonishing career as a child actor at 6 years old he lived to give his name to the firm of W. R. Grossmith, of Burleigh-street, Strand, which continues to make artificial limbs under its auspices. William Robert Grossmith (1818-99) was the elder brother of George Grossmith, the journalist and entertainer, who founded the branch of the family celebrated as humorists and actors. In many ways William was the more remarkable child. His abilities astounded his family before he could lisp, and when he was 6 years old his father took him to London to see James Jones, the founder of the Coburg Theatre, which has now become the Old Vic. Jones was so struck with his precocity and brilliance that he was allowed to appear at the Coburg in 1824 with songs as a Jew and as a country bumpkin. In a later appearance as Richard III. he got an excellent press. Even the *Times* was moved to remark: "We were much gratified with the performance of the Infant Grossmith, who really exhibits a most wonderful theatrical talent, and which, if well cultivated, will at a future period produce some brilliant acting." He then performed for a week each at the Surrey and Sadler's Wells; but his father declined further engagements, and he returned home. His development could not, however, be stayed, and in a short time he increased his repertory to include violin-playing, recitations, and mimicry, the acting of several Shakespearean characters, and the playing of "musical glasses." A small movable theatre was built for him and he set out on a series of tours of England, starting in his native town, where he entertained 300 people for nearly three hours with dance, drama, and song. His remarkable powers won him the title of The Young Roscius, in contrast to that of The Infant Roscius, conferred on William Betty (1791-1874), who made a fortune and retired at 17. Grossmith became so famous that a short book ("The Life and Theatrical Excursions of William Robert Grossmith, the juvenile actor, not yet nine years of age," 1827, Reading) ran through at least two editions. It is not known when he left the stage, although it is certain that he did not continue on it in manhood. He was apprenticed to the business of an artificial limb-maker with John Henry Sleath, the inventor of the kneeling artificial knee, who had started business in 1760. Grossmith succeeded to the business in 1813, and in 1857 set forth his story in a pamphlet entitled "Amputations and Artificial Limbs," dedicated to William Lawrence, F.R.S., President of the Royal College of Surgeons. He became a charming old man, and throughout his life retained the sense of humour which had made him a comedian at six years of age.

RIVIERA TRAVEL.

THE Sleeping Car (Wagons-Lits) Company announces the preliminary arrangement for its winter service from Calais direct to the Riviera. The Calais-Mediterranean Express (the Blue Train) will commence running in connexion with the 10.45 A.M. Pullman train from Victoria on Friday, Nov. 6th, and will run via Paris until Feb. 9th, after which date it will run daily direct from Calais to the Riviera without calling in Paris, a separate "Blue Train" being run from Paris daily from Feb. 10th. Six other daily services will run to the Riviera from Calais, and from Paris, with improved sleeping cars. Plans for the return journeys of these services will be kept in London to enable passengers to secure the required accommodation for the homeward journeys before leaving London. Bookings may be made at 20, Cockspur-street, London, S.W. 1.

APPARATUS FOR ACTINO-THERAPY.

WE have reached the season when the sun is below the horizon for half or more of the 24 hours, and the oblique rays, even when there is no cloud, are largely absorbed by water-vapour and atmospheric impurities. Hence all the supplies of artificial light are of enhanced value.

The tungsten arc lamp made by the Medical Supply Association (167-185, Grays Inn-road, London, W.C. 1.) is very well and elaborately constructed, and is useful for ultra-violet radiation when only a low amperage current is available. The electrodes used are either carbon or tungsten. The method of interchanging the electrodes could be simplified. The electrodes are adjusted by a simple, hand-controlled, regulating screw, and a spring release for adjusting the distance between them. This gives a steady burning arc, but the length of the flame and voltage across the arc varies as the carbons burn away. The lamp is made of a highly polished metal; the inner side of the lamp reflector tarnishes rapidly and gets a white deposit of metallic salts, which is difficult to clean. The focusing of the arc is not well centred, and the arrangement of the quartz lens adapter for localised treatment might be improved. The ultra-violet energy is good for near distances up to 18 in., but falls off rapidly beyond 24 in., owing to the diffused scattering of the rays.

The mercury-vapour lamps manufactured by Messrs. Kelvin, Bottomley and Baird, Ltd. (51-52, Fenchurch-street, London, E.C. 3) are of the atmospheric type. When the current is switched on, the arc is started by means of a small heating coil which surrounds a limb of mercury projecting from the arc tube. The mercury is heated up in this limb by means of the heating coil; when the mercury boils the arc is established, and the heating coil is automatically cut out of the circuit. Lamps of many descriptions and different shapes are made for local and general light treatment. They are very steady in burning and require no attention when started. The ultra-violet energy is very high, and is very constant. The quartz is made by the Thermal Syndicate, and is of a good quality. The lamp is economical and easy to run, and shows very little deterioration with prolonged use. Up to the present such lamps can only be made for direct current, but it is anticipated shortly to supply alternating current burners. The K.B.B. lamps are exceptionally useful for all work when a steady and constant service of ultra-violet energy is required.

The Hilger spectrometer is a useful apparatus for detecting ultra-violet rays in artificial sources of light. The spectroscope is a small type, and the rays after passing through the system of prisms is focused on to a uranium glass. The apparatus is still in an experimental stage, and many small alterations are necessary before it will be possible easily to adopt its use.

The interesting catalogue of the Cox-Cavendish Electrical Co., Ltd. (105, Great Portland-street, London, W.,1), collects together the most useful types of lamps now available for artificial sun treatment. It is of great guidance to the practitioner, and each type of apparatus is clearly described and well illustrated. Every endeavour is made to indicate the advantages and best way of utilising these lamps. The catalogue includes all the standard types of lamps, and should be of great assistance in helping to provide for "light" clinics. The literature is well produced, and much useful reference to current literature is adopted. The description of the flaming open carbon arc is clearly expressed and the biological standards are quoted. It is a complete and briefly classified catalogue on photo-therapy.

figures representing the Norwegian output, for which I am indebted to H.B.M. Consul at Bergen, it will be seen that there is generally an inverse relationship. This opens up an economic question which it is inappropriate to discuss here, but it is certain that Newfoundland could supply much larger quantities of oil for medicinal use in this country if its uniformly high nutritive value were sufficiently appreciated by the medical profession and the public.

The fish are caught over a wide area, extending beyond the North Sea to the Faröe Islands, Iceland, and even as far as the White Sea. Probably no great proportion of spawning fish are present in the catch, even in the early months of the year, but we have no definite information on this point. It is certain, from a considerable number of samples that we have examined, that cod-liver oils of good trade quality and high medicinal value can be placed on the market by manufacturers in this country if they are prepared to go to the trouble of working up the livers immediately after the fish are caught. Usually this means the installation of steaming plants, which, however, may be of very simple construction on the trawlers, as the majority of the boats are away from port for periods of from one to six weeks.

PUBLIC HEALTH IN BOMBAY.

THE population of Bombay at the 1921 census numbered 1,175,914, and at the middle of 1923 was estimated at 1,220,120, on which latter figure the birth and death ratios have been calculated. The birth-rate was 17·20 per 1000; or, if calculated on the census population, the ratio would be 17·85. In that year the birth ratio for the Presidency, as a whole, was 33, and for the city 16. The explanation of this low ratio is stated by Dr. J. E. Sandilands, Executive Health Officer, who presents this report, to be due partly to the custom whereby married women leave the city for their confinement, and so register their children in the mofussil districts where they are born, and partly because some births in the city are not registered. 1487 births were inquired into in 1922 and 1923, and it was found that 63 per cent. only of these infants were born in Bombay, 37 per cent. having been born elsewhere; and, out of 8632 infantile deaths during the year, 31 per cent. occurred in children who had been born outside the city. "Of the infants living and dying in the city it may therefore be assumed that, roughly, one-third were born elsewhere"; if added to the numbers registered, the birth-rate would be increased from 17 to 26 per 1000. The total birth-rate being, however, assumed to be 17·20 per 1000, the variation among different castes ranged from [illegible] and 6·50 [illegible] caste [illegible] and Lingaits is obviously due to an understatement of the Lingait population in the census returns." The registered births numbered 146, and the deaths 339; the Lingait population is stated to be 866. Disregarding this group, the death-rate varied from 8·81 among Banias, and 11·45 among Europeans, to 29·24 for Hindus of all castes, 32·10 for Indian Christians, 34·23 in Jains, 34·89 in Anglo-Indians, and 48·73 in Mussulmans. Jains suffered most heavily from plague (2·75 deaths per 1000), the general plague mortality being only 1·08 per 1000; for Hindus of all castes 1·20, and for Europeans 0·13. "The liability to plague is not improbably due to the fact that Jains do nothing to prevent rats entering and living in their houses." Enteric fever was most fatal to the Parsees (0·64), Bhatias (0·53), and Europeans (0·45), the general enteric mortality being only 0·11 per 1000.

Mortality from All Causes.

In regard to the mortality from all causes in the different wards and sections of the city, the ratios varied from 16·56 per 1000 (Fort South section of Ward A), and 19·05 (Walkeshwar in Ward D), to 36·90 in Worli section (Ward G), and 42·06 in 2nd Nagpada section (Ward E). The infantile mortality varied from 236 per 1000 births in 1st Nagpada section of Ward E, and 264 in Walkeshwar section (Ward D), to 521 in 2nd Nagpada (Ward E), also in Mandvi (Ward B), 534 in Sion section (Ward F), and 548 in Byculla (Ward E). As the registration of births is faulty, the infantile deaths in relation to the *total population* at all ages are separately stated. This ratio varied from 1·86 per 1000 in Fort South (Ward A) to 9·77 in Byculla section (Ward E), and was 7·07 for the city as a whole. The excessive mortality is largely due to overcrowding; 14,302 births (68 per cent. of the total) took place in families living in a single room or sharing it with others, the infantile mortality being 524·4 per 1000 births. In families occupying two rooms the mortality was 394·5; in three rooms, 255·4; in four or more rooms, 240·5; in hospitals, only 112·2. Much work has been done to remedy this deplorable state of things by visits of nurses, attendance on confinements, provision of necessaries, of maternity homes, milk depôts, and infant welfare centres. The municipal nurses paid 54,[illegible]02 visits, and attended 1914 confinements. Besides this 1[illegible]73 cases were admitted to the municipal maternity homes; two infant milk depôts have been established, and the Maternity and Child Welfare Scheme of the Infant Welfare Society has made much progress.

Infectious Diseases.

The notifications of infectious diseases numbered 4575, of which total 1501 were for plague, 1274 for tuberculosis, and 978 for small-pox. Plague was epidemic from Feb. 17th to June 2nd, and caused 1320 deaths (1·08 per 1000 population, as compared with 0·67, the quinquennial average). Of these 1202 occurred within the dates mentioned. The case mortality was 89 per cent. No fatal cases occurred in 1st Nagpada section of E Ward, and only one in Upper Colaba. All the other sections suffered more or less, most deaths occurring in Worli (251) and Mahim (172) sections (both in G Ward); and the highest mortality ratios falling on Mahim (3·31), Mahalakshmi (2·[illegible]2), and Worli (1·98 per 1000). The usual preventive and precautionary measures were continued during the year; infected dwellings were evacuated and disinfected, and temporary health camps established; 13,749 inoculations were performed; 725,574 rats destroyed, of which 305,283 were examined at the Parel laboratory, 2·77 per cent. being found to be infected. The percentage of infection rose from 1·63 in January and 3·55 in February to 6·75 and 7·42 in March and April. It then declined to 2·10 in June and 1·27 in July, and was below 1·0 per cent. for the rest of the year.

Small-pox was prevalent throughout the year, 978 cases being registered, of which 470 were fatal, compared with 130 cases and 61 deaths in 1922. The mortality ratio was 0·39 per 1000, as compared with 0·48, the quinquennial average. No fatal cases occurred in Upper Colaba. In the other sections the mortality was below 1·0 per 1000 in all except 1·04 in Fanaswadi (C Ward) and 1·21 in Chowpati (D Ward). The total primary vaccinations performed numbered 20,293, of which 97·65 per cent. were known to be successful. In addition, 21,725 persons were revaccinated. Of the 87 infants under 1 year of age who died from small-pox 65 were not vaccinated, and one was vaccinated during the incubation period. In the remaining cases the vaccinal condition was not ascertained, a most regrettable omission.

Cholera was much more prevalent in the city than in the previous year. There were 323 attacks and 180 deaths, as compared with 22 and 15 in 1922; 41 of the cases were imported. No fatal cases occurred in Upper Colaba, Fort South, 2nd Nagpada, 1st Nagpada, or Sion sections. In the remainder, 39 deaths occurred in Market section, and 43 in the adjoining Dhobi Talao, giving death ratios of 1·08 and 1·00 per 1000 respectively. There were two outbreaks. The first (June 6th to 27th) occurred among the Mohammedan pilgrims, coming from distant provinces and proceeding to Mecca; 16,001 passed through Bombay. They were accommodated as far as possible in three "Mussaferkhanas"; but as these buildings could not hold as many as 3000, many pilgrims had to be lodged in hired buildings with inadequate sanitary arrangements, or were encamped on the open spaces outside the Mussaferkhanas. Two cholera cases occurred in pilgrims arriving from infected provinces. During the month there were 25 attacks and 17 deaths. Sanitary measures were carried out, and 5965 pilgrims were inoculated with anticholera "vaccine"; the spread of the disease was checked. The second outbreak occurred among the city residents. There were 274 attacks and 155 deaths between July 16th and the end of August. The disease had prevailed in Poona, Ahmednagar, and other parts of the province, and "ample opportunities existed for the introduction of infection from the outside." Chlorination of the water-supplies was carried out, and inoculation stations opened, where 1710 persons were treated.

Influenza was registered as causing only 250 deaths (0·20 per 1000), as compared with 1·77 per 1000, the quinquennial average; but respiratory diseases, to which influenza deaths are frequently attributed, caused 14,099 deaths, as compared with 18,014 in the previous year. Tuberculosis caused 1371 deaths (1·12 per 1000), a satisfactory continuation of the improvement during recent years. In the decennium 1913–22, the mortality had averaged 1·95, and in 1922 it was 1·23 per 1000. The work carried on by the King George V. Antituberculosis League was taken over by the municipality in July. There are two dispensaries in the city, and a sanatorium with 32 beds on Bholwada Hill, Parel, known as the Turner Sanatorium; 1120 cases were treated at the dispensaries, and the medical officers visited 1238 patients too ill to attend personally.

Malaria was registered as the cause of 403 deaths, the diagnosis being verified in each case. In addition 2603 deaths were returned as due to "Ague and Remittent Fevers"; many of these may have been due to typhoid, tuberculosis, or influenza, in which fever may be a prominent symptom. Spleen examinations (10,553) were carried out among children in all of the 31 sections of the city except four (Kamatipura, Parel, Sewri, and Mahim). No splenic enlargement was found among 126 children in Fanaswadi section of Ward C. The total cases of enlargement numbered 936 out of 10,553 children examined, the ratios varying from 1·2 per cent. in Kumbharwada and 1·4 in Bhuleshwar (both in Ward C), to 10·07 in Tarwadi (Ward E), 10·86 in Fort South (Ward A), 18·7 in Sion (Ward F), 14·88 in Fort North, and 16·82 in Colaba (Ward A). It is regrettable to find that, in the report of the municipal laboratory, out of 1267 milk samples analysed 41·3 per cent. were adulterated. In Ward F the ratio was 62·0, and in Ward G 70·6 per cent.

AN UNUSUAL CAREER.

INFANT prodigies are always interesting in their infancy, but very few of them remain at all noteworthy in their later years. William Robert Grossmith, the son of a Reading picture-frame maker, was something of an exception to this rule. After an astonishing career as a child actor at 6 years old he lived to give his name to the firm of W. R. Grossmith, of Burleigh-street, Strand, which continues to make artificial limbs under its auspices. William Robert Grossmith (1818–99) was the older brother of George Grossmith, the journalist and entertainer, who founded the branch of the family celebrated as humorists and actors. In many ways William was the more remarkable child. His abilities astounded his family before he could lisp, and when he was 6 years old his father took him to London to see James Jones, the founder of the Coburg Theatre, which has now become the Old Vic. Jones was so struck with his precocity and brilliance that he was allowed to appear at the Coburg in 1821 with songs as a Jew and as a country bumpkin. In a later appearance as Richard III. he got an excellent press. Even the *Times* was moved to remark: "We were much gratified with the performance of the Infant Grossmith, who really exhibits a most wonderful theatrical talent, and which, if well cultivated, will at a future period produce some brilliant acting." He then performed for a week each at the Surrey and Sadler's Wells; but his father declined further engagements, and he returned home. His development could not, however, be stayed, and in a short time he increased his repertory to include violin-playing, recitations, and mimicry, the acting of several Shakespearean characters, and the playing of "musical glasses." A small movable theatre was built for him and he set out on a series of tours of England, starting in his native town, where he entertained 300 people for nearly three hours with dance, drama, and song. His remarkable powers won him the title of The Young Roscius, in contrast to that of The Infant Roscius, conferred on William Betty (1791–1874), who made a fortune and retired at 17. Grossmith became so famous that a short book ("The Life and Theatrical Excursions of William Robert Grossmith, the juvenile actor, not yet nine years of age," 1827, Reading) ran through at least two editions. It is not known when he left the stage, although it is certain that he did not continue on it in manhood. He was apprenticed to the business of an artificial limb-maker with John Henry Sleath, the inventor of the kneeling artificial knee, who had started business in 1790. Grossmith succeeded to the business in 1843, and in 1857 set forth his story in a pamphlet entitled "Amputations and Artificial Limbs," dedicated to William Lawrence, F.R.S., President of the Royal College of Surgeons. He became a charming old man, and throughout his life retained the sense of humour which had made him a comedian at six years of age.

RIVIERA TRAVEL.

THE Sleeping Car (Wagons-Lits) Company announces the preliminary arrangement for its winter service from Calais direct to the Riviera. The Calais-Mediterranean Express (the Blue Train) will commence running in connexion with the 10.45 A.M. Pullman train from Victoria on Friday, Nov. 6th, and will run via Paris until Feb. 9th, after which date it will run daily direct from Calais to the Riviera without calling in Paris, a separate "Blue Train" being run from Paris daily from Feb. 10th. Six other daily services will run to the Riviera from Calais, and from Paris, with improved sleeping cars. Plans for the return journeys of these services will be kept in London to enable passengers to secure the required accommodation for the homeward journeys before leaving London. Bookings may be made at 20, Cockspur-street, London, S.W. 1.

APPARATUS FOR ACTINO-THERAPY.

WE have reached the season when the sun is below the horizon for half or more of the 24 hours, and the oblique rays, even when there is no cloud, are largely absorbed by water-vapour and atmospheric impurities. Hence all the supplies of artificial light are of enhanced value.

The tungsten arc lamp made by the Medical Supply Association (167-185, Grays Inn-road, London, W.C. 1.) is very well and elaborately constructed, and is useful for ultra-violet radiation when only a low amperage current is available. The electrodes used are either carbon or tungsten. The method of interchanging the electrodes could be simplified. The electrodes are adjusted by a simple, hand-controlled, regulating screw, and a spring release for adjusting the distance between them. This gives a steady burning arc, but the length of the flame and voltage across the arc varies as the carbons burn away. The lamp is made of a highly polished metal; the inner side of the lamp reflector tarnishes rapidly and gets a white deposit of metallic salts, which is difficult to clean. The focusing of the arc is not well centred, and the arrangement of the quartz lens adapter for localised treatment might be improved. The ultra-violet energy is good for near distances up to 18 in., but falls off rapidly beyond 24 in., owing to the diffused scattering of the rays.

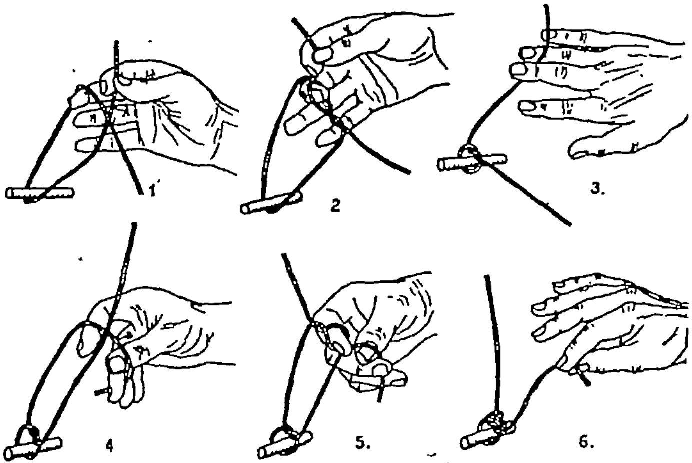
The mercury-vapour lamps manufactured by Messrs. Kelvin, Bottomley and Baird, Ltd. (51–53, Fenchurch-street, London, E.C. 3) are of the atmospheric type. When the current is switched on, the arc is started by means of a small heating coil which surrounds a limb of mercury projecting from the arc tube. The mercury is heated up in this limb by means of the heating coil; when the mercury boils the arc is established, and the heating coil is automatically cut out of the circuit. Lamps of many descriptions and different shapes are made for local and general light treatment. They are very steady in burning and require no attention when started. The ultra-violet energy is very high, and is very constant. The quartz is made by the Thermal Syndicate, and is of a good quality. The lamp is economical and easy to run, and shows very little deterioration with prolonged use. Up to the present such lamps can only be made for direct current, but it is anticipated shortly to supply alternating current burners. The K.B.B. lamps are exceptionally useful for all work when a steady and constant service of ultra-violet energy is required.

The Hilger spectrometer is a useful apparatus for detecting ultra-violet rays in artificial sources of light. The spectroscope is a small type, and the rays after passing through the system of prisms is focused on to a uranium glass. The apparatus is still in an experimental stage, and many small alterations are necessary before it will be possible easily to adopt its use.

The interesting catalogue of the Cox-Cavendish Electrical Co., Ltd. (105, Great Portland-street, London, W., 1), collects together the most useful types of lamps now available for artificial sun treatment. It is of great guidance to the practitioner, and each type of apparatus is clearly described and well illustrated. Every endeavour is made to indicate the advantages and best way of utilising these lamps. The catalogue includes all the standard types of lamps, and should be of great assistance in helping to provide for "light" clinics. The literature is well produced, and much useful reference to current literature is adopted. The description of the flaming open carbon arc is clearly expressed and the biological standards are quoted. It is a complete and briefly classified catalogue on photo-therapy.

A "SINGLE-HANDED" SQUARE KNOT.

Dr. F. G. Meynen, in a current issue of the *Journal of the American Medical Association* (August 22nd, p. 579), describes a simple and easy method of tying a square knot which, once the knack is acquired, possesses the following advantages: It is rapid and cannot fail to tie "square"; only one hand (the right) is directly used; at no time is it necessary to drop either end of the suture—each movement leading naturally with the succeeding one without rearranging the grasp. It is adaptable to all purposes and positions. Dr. Meynen describes the procedure thus: "It is essential to remember that the long end (if there is a choice) should always be grasped by the left hand. In the drawings, for the sake of simplicity, the long end is left free without indicating the left hand. Assuming that the long end comes out of the wound on the far side from the surgeon about to tie the knot (as is the case, for example, when the first knot in a continuous suture is tied by an assistant for the operator), it is grasped by the left hand, while the short end is grasped about 1 inch from the end between the thumb and index finger of the right hand with the palm down. The palm is immediately turned upward with the suture lying across the fingers and the longer end brought into the position shown in Fig. 1. The middle finger is then hooked under the portion of the suture marked *A*, as in Fig. 2; this is drawn through the loop by grasping it between the middle and ring fingers, and first single knot drawn tight as in Fig. 3. The same firm grasp being kept with the middle and ring fingers, the palm is turned somewhat upward, the thumb and first finger being placed under the suture and the long end in the position shown in Fig. 4. The tip of the index finger is then hooked under the portion marked *B*, as in Fig. 5, drawing it through the loop and grasping it between the thumb and index finger as soon as it is through, and the knot is drawn tight and completed as in Fig. 6. Should a third knot be desired, the hand will be found in a position ready to repeat the first manœuvre from Figs. 1 to 3. Should the surgeon be desirous of tying his own suture (in which case the short end will come out on the far side of the wound and the long end on the near), he has only to begin with the manœuvres depicted in Figs. 3 to 6 and end with Figs. 1 to 3.



Steps in tying the knot.

"This method is particularly suitable and rapid for ligating vessels with a long ligature wound around the fingers of the left hand. It must be remembered, however, to begin with Fig. 1, when the long end comes up on the far side of the clamp, and with Figs. 3 to 6 and then Figs. 1 to 3 when the long end comes up on the near side of the clamp. This decision will come instinctively with practice. The knot can be tied easily in two seconds."

"DORMA" EAR PADS.

THESE pads are designed to relieve sufferers from head noises. They are to be placed in front and behind the ear—there are both single and double pads—where they are retained in position by elastic bands. A point is made of the free circulation of air between the meatus and the pillow on which the patient is resting, and it is claimed that throbbing noises due to heart action, which are sometimes very distressing, are much or wholly suppressed. Under the advice of a medical man the apparatus should prove useful, and our readers might have cases in which they could be employed. The apparatus in the single form costs 15*s*., and in the double form 25*s*., from the Dorma Manufacturing Co., 25 and 27, Quadrant Chambers, New-street, Birmingham.

THE UNMARRIED MOTHER.

THE National Council for the Unmarried Mother and her Child, which has issued its seventh annual report, has to contend against public apathy, and against those whose anxiety for public morality makes them pretend that unmarried parents do not exist. There are also those who think illegitimate children poor specimens best out of the world; those who would fight for the child's welfare, but care nothing for the mother, and those who wish to "rescue" the mother but would allow the child to be adopted. The Council is strongly against separation of the mother and child, from the point of view of both. The death-rate of illegitimate children in their first year (132 per 1000 births in 1923 in England and Wales) is twice that of children born in wedlock, and the Council attributes this partly to artificial feeding or early weaning encouraged by the idea that the child can be adopted. Besides activity on behalf of actual cases—628 during last year—the Council is attempting to get the existing Bastardy and Affiliation Acts reformed. The Legitimacy Act, now almost law, and Captain Bowyer's Bastardy Bill represent some of its aims, which include the hearing of affiliation cases before the child's birth, payment by the father towards pregnancy and confinement expenses, and improvement of the legal position of adopted children. The offices are at Carnegie House, 117, Piccadilly, London, W. 1.

A USEFUL CATALOGUE.

WE have received from Messrs. May and Baker, Ltd., Battersea, London, an interesting catalogue of their pharmaceutical specialties. The catalogue gives information concerning a number of pharmaceutical products supplied by the manufacturers which have been noted in our columns at different times. The indications for the employment and the technique for the administration of such well-known drugs as arsenobillon, novarsenobillon, and stovarsol are clearly set out, the last two preparations of the firm having been tested biologically by the Medical Research Council and approved by the Ministry of Health. The firm supplies also vaccines for the treatment of gonorrhœa which have been prepared by the pathological laboratory of the London Lock Hospital, as well as some well-known preparations of bismuth.

THE PRIVATE COUNSELLOR.[1]

IN writing this work the author's desire has been to provide the layman with a book dealing with the more common diseases and derangements of the male generative organs. That there is a deplorable amount of ignorance on the subject of sex with much resulting harm we are convinced. At the same time it is probable that this work by an anonymous medical writer will in the end leave his readers in a worse state than that in which it found them. The pages contain vivid descriptions of the ravages of untreated syphilis and of the deplorable condition of individuals who persist in self-abuse. Thus, in the chapter on syphilis we hear that this disease "breaks down the vigorous and lusty youth, covering the body with loathsome ulcers or destroying the bones, and thus defacing the manly beauty of the human face divine." We fear that the work is calculated to precipitate a breakdown in the person whom it is intended to help. A morality built on fear is a poor thing, and fear is the mainspring of this work. Even if the author does not intend to frighten he will do so. No layman can read a medical work without the risk of believing himself to be the victim of some of the disorders described within its covers, and many a sexual neurosis has resulted from an unwise excursion into medical literature. Whilst believing that the author's intentions are excellent, we deplore the result of his efforts.

Col. J. S. Riddell, A.M.S. (T.), O.B.E., M.V.O., has been appointed a Deputy-Lieutenant for Aberdeen.

T. L. A., with whose views we have considerable sympathy, has omitted to enclose his address.

T. D.—There seems no room for hypnotic phenomena in the interesting case related, although hypnotists have been known to use light chloroform anæsthesia to aid the induction of a hypnotic state. The case is probably one of a delusional system related to paranoia, inasmuch as intellect is unimpaired and there are no neurotic symptoms. Time will show.

---

THE
Origin and Significance
OF
POSTURAL (ORTHOSTATIC) ALBUMINURIA.

By JAMES W. RUSSELL,* M.D. Camb., F.R.C.P. Lond.,

PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL; JOINT PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BIRMINGHAM.

By *the term postural (or orthostatic) albuminuria* I mean nothing more than an albuminuria which develops in the upright position and ceases when the patient lies down. It is commonly used to imply a special form of albuminuria, "functional" or mechanical in origin, constituting a more or less defined clinical condition and tending to affect a special type of patient—children or young adults, often of poor physique, with low blood pressure and cold extremities, excreting globulin in excess of albumin. Whilst admitting the convenience of using the name only for the cases in which urine secreted in bed is free from albumin, I do not agree that the condition is always "*functional*" in nature, or is to be found in any particular type of patient, and I think that the limitation of the conception of the effect of posture on albumin excretion to the cases in which the bed urine is entirely free from albumin robs the symptom, as I would prefer to regard it, of much of its significance. The object of this paper, the outcome of five years' study of the subject, is to bring forward evidence in favour of the view that many cases of purely orthostatic albuminuria are the result of infection, and secondly to establish the point that the orthostatic reaction, in the true sense of the term, is common alike to the supposedly functional cases and to most, if not all, cases of nephritis, and, indeed, possibly to most forms of albuminuria.

In the *Quarterly Journal of Medicine*, January, 1923, I published a study of a series of cases of orthostatic albuminuria, based upon graphic records of the albumin output. The results were not altogether in accordance with the views usually held as to the functional nature of these cases, and it was especially noted that the orthostatic response, in nearly all its features, was met with in certain cases of mild nephritis. On this, as well as on other grounds, the provisional suggestion was made that orthostatic albuminuria might, in some instances at any rate, be the outcome of a past renal infection of mild degree. Since writing that paper I have continued to investigate all the cases of the condition occurring in my wards and in private practice, and I have now some fresh evidence to offer in support of the suggestion.

METHOD OF MEASUREMENT OF ALBUMIN.

The albumin measurements recorded in the *Quarterly Journal* and in the present communication have all been obtained by the method of estimation described in detail in the former paper, and more briefly in THE LANCET of Oct. 27th, 1923. Its advantages are that it makes possible the measurement of any quantity of albumin, down to the smallest trace. It would take too long to repeat here the description of the method. I may merely say that it depends upon the number of dilutions needed to reduce a cloud of coagulated albumin to the point at which it matches a standard haze. Further that the standard I now use is made by mixing together half a cubic centimetre each of a 0·014 per cent. solution of barium chloride and magnesium sulphate respectively, and adding, after the haze has developed, 10 c.cm. of distilled water pigmented so as to imitate the colour of a pale urine. (The solutions are kept in bottles previously treated with strong hydrochloric acid in order to neutralise the alkali of the glass.) The haze so produced constitutes the "unit" of albumin, and is practically the smallest haze recognisable in a good light against a dark background. For various reasons it is inadvisable to assign to the unit any absolute value. The object aimed at is the study of the relative output of albumin under different conditions and at different times; the absolute amount passed is rarely a matter of importance. Indeed, it is open to each observer to work with the unit with which he feels that he can obtain the most accurate results, and with myself this is the smallest recognisable haze. Although, in order to save reproduction, only two charts are included in this paper, all the cases recorded have been studied by means of exact observations obtained in this manner.

THE ORTHOSTATIC REACTION.

I will not burden my paper with any long account of the natural history of the orthostatic reaction. It will be enough to enumerate the chief features, as follows: The urine secreted in bed is ordinarily free from albumin, whilst that of the upright position is more or less albuminous, the amount of albumin varying directly with the time spent in the upright position, and in inverse direction, though not, I think, exactly in inverse amount, with the quantity of urine in process of secretion. Artificial lordosis, produced in bed by means of pillows, may or may not give rise to the passage of albumin, but standing upright usually, and standing in the position of lordosis invariably, produces an albuminuria, except during a period of diuresis. Standing in the leaning forward position abolishes the excretion of albumin.

SOURCES OF FALLACY.

There are two sources of fallacy with which I must deal before recording my evidence, inasmuch as they often interfere with the recognition of cases that are strictly orthostatic in nature, and one, at least, may easily lead to misinterpretation of my results.

(1) It is usually held that the urine passed immediately on getting out of bed by a patient suffering from orthostatic albuminuria is invariably free from albumin, and that any deviation from this behaviour excludes the case from the orthostatic group. But this statement is untrue of many genuine cases, and for an obvious reason. The albuminuria set going by the upright position continues, and sometimes increases, for half an hour or more after the return to bed, and Chart 1 shows what often happens when a patient, the subject of a postural albuminuria, gets out of bed, stands for a few minutes, and then resumes the lying-down position. In this case a boy with an obvious orthostatic albuminuria got out of bed and passed albumin-free urine. He then stood for seven minutes, returned to bed, and passed urine as soon as possible afterwards. This urine was highly albuminous. Twenty minutes later he again passed urine, being still in bed, and this urine was yet more albuminous than before. An hour after the return to bed a trace of albumin was still present. An actual increase in the albumin excretion on lying down does not always occur, and probably does not take place at all when the patient goes to bed at the end of the day with a definite albuminuria. (This he generally does, for the cessation of the albuminuria during the late afternoon and evening, supposed to characterise the orthostatic cases, is, according to my experience, altogether the exception.) But the albuminuria with which he goes to bed continues for half an hour or more after lying down, though gradually diminishing, and the retention in the bladder of this albuminous urine contaminates the night's collection and registers itself in the morning urine as a definite haze. The case is then apt to be wrongly rejected as one in which the albuminuria is not of the orthostatic variety.

This point is of sufficient importance to bear illustration by two cases.

---

* An obituary notice of the late Dr. Russell, who died shortly after this paper reached us, appears in another column.—Ed. L.

A lad, aged 16, in whom an albuminuria had been discovered *on routine examination preliminary to application for admission into the Air Force*, was admitted into the Birmingham General Hospital under Dr. L. G. Parsons, to whom I am indebted for the opportunity of examining him. The albuminuria had been regarded as almost certainly of the postural variety, but *a small amount of albumin had been* persistently present in the night's collection of urine—he was up and about all day.§ On May 2nd–3rd the following *observations* were *made* :—

	c.cm. urine.		Albumin units.
9 P.M.—On going to bed	20	......	375
11 P.M.—Two hours after lying down	120	......	18
7 A.M.—On getting up	230	......	0
9 A.M.—Two hours up	30	......	220

On this occasion the bladder was emptied afresh two hours after going to bed and the morning urine was then free from albumin. Had the 11 P.M. urine been retained, the *morning specimen* would *have* contained from 6 to 7 units of albumin, a small, but quite recognisable haze.

CHART 1.

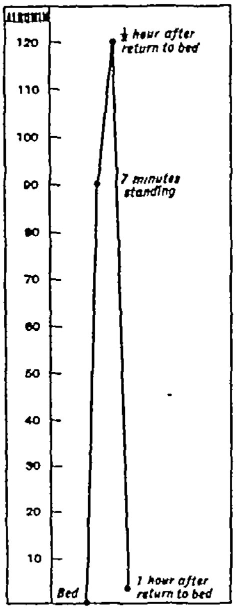

CHART 2.

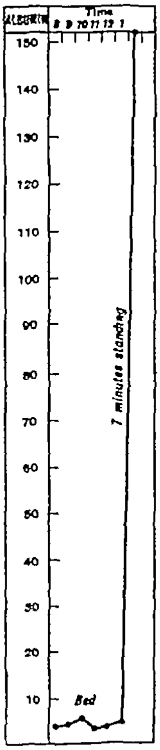

The second case was that of a girl, aged 11, who was in my ward in May, 1924, with a postural albuminuria of large degree. A year later she was readmitted for further investigation, and now the morning urine regularly contained a haze of albumin. But on April 11th, after being up all day, she went to bed with an albuminuria of 90 units, and an hour later was made to pass urine again. Next morning the night's collection was entirely free from albumin.

This source of fallacy will receive further illustration in others of my cases. It is one that is not, I think, generally recognised, but unless it is kept in mind many strictly orthostatic cases will pass undiagnosed.

(2) The second source of fallacy lies in the fact that during diuresis the upright position loses its effect on the excretion of albumin. For this reason in a suspected orthostatic case it is never safe to depend upon the absence of albumin from a single plentiful specimen of urine. And even in the absence of diuresis it must always be remembered that the sitting posture also abolishes the albuminuria.

INFECTIVE ORIGIN OF MANY CASES OF ORTHOSTATIC ALBUMINURIA.

In the paper already referred to the first case studied was that of a girl in whom the albuminuria had first been discovered immediately after an attack of diphtheria. I have now to bring forward evidence pointing to a connexion between the orthostatic condition and a past attack of scarlet fever. I am aware that the origin of the condition in a former attack of scarlatinal nephritis has often been suggested, but, as will be seen, that is not exactly my contention.

CASE 1.—I am indebted to Dr. H. Savage, my former house physician, for bringing this case to my notice, and for permission to publish the details. The patient was a girl, aged 8, who was seen by him when in practice in Coventry. Two months previously the child had been admitted into *the Fever Hospital with an attack of scarlet fever, and she* was discharged at the end of six weeks, without any known abnormality of the urine. A week after her return home she was brought to Dr. Savage with œdema of the left leg and the left side of the face; the urine contained a thick cloud of albumin, and casts were found in the deposit. The girl was put to bed, and the œdema and albuminuria *at once came to an end. After a further period of rest in* bed the œdema did not return on getting up, but from that time, whilst the bed urine was invariably free from albumin, 10 minutes' standing always produced a definite cloud. On Dec. 2nd, 1923, some four months after the onset of the fever, two specimens of urine were brought to me for examination. One, passed immediately after getting out of bed in *the morning, was quite free from albumin. The other*, passed soon after standing upright for 10 minutes, contained 110 units, a fairly thick cloud. On occasions, during the next 12 months, further specimens were examined with the same result, but by the end of 1924 the immediate response *to standing had practically ceased*. Whether or not the urine of the rest of the day was albuminous I do not know, *as the case passed out of reach*.

CASE 2 was that of a young man, aged 25, who contracted scarlet fever in the army in 1918. He was treated for six *weeks in the Fever Hospital*, and was discharged without any suspicion of renal disease. A fortnight later he was examined for some routine purpose and albumin was discovered in the urine, and eventually he was discharged from the army with the diagnosis of nephritis. From that time onwards his doctor had found an "intermittent albuminuria." He consulted me in May, 1925. The blood pressure was 85/142, but I thought that the rather high systolic reading might be partly the result of excitement. The heart was not recognisably enlarged and I could find no casts in *the urinary deposit. On May 23rd he sent me a series of* specimens of urine passed at hourly intervals throughout the morning, together with one passed on going to bed the night before, with the following results :—

		c.cm. urine.		Albumin units.
11 P.M.—On going to bed..	..	42	......	90
8 A.M.—On getting up ..	..	300	......	6
9 "	..	35	......	70
10 "	..	46	......	65
11 "	..	40	......	70
12 noon	..	55	......	36
1 P.M.	..	50	......	28

The trace of albumin in the early morning specimen is easily explained by the fact that the urine was heavily loaded *at bedtime the night before, and the bladder had not been* emptied again during the night.

The two following cases suggest that a definite scarlatinal nephritis may ultimately be represented by a postural albuminuria.

CASE 3.—A girl, aged 13, was *sent into* my ward on account of an albuminuria discovered in the out-patient room. Two years previously she had had an attack of scarlet fever and her mother was informed that the kidneys were slightly affected and that the urine was "not quite right." The albuminuria was entirely postural in occurrence, though the immediate response to standing was but slight.

CASE 4 was that of a young man, aged 24, who consulted me for "nephritis." At the age of 10 he had had an attack of scarlet fever which was not at first diagnosed. In consequence he went about *for some* days and a nephritis developed. From that time albumin had been almost always found in the urine, and a year ago a very serious prognosis had been given. When I saw him in May, 1924, he was somewhat pale and complain*ed of being easily tired*. The heart was not enlarged and the blood pressure was 80/130. The urine passed in my room contained a cloud of albumin, but neither in this specimen nor in others subsequently examined was I able to find any casts. Next morning the urine passed on getting out of bed contained 8 units of albumin, and 10 minutes' standing produced a dense cloud of over 500 units. On other *occasions* the same trace of albumin was found in the bed urine, but that this was due to the continued excretion of albumin during the first period after getting to bed at night is shown by the fact that on one occasion when the bladder was emptied afresh an hour after lying down the urine next morning was absolutely albumin-free.

Post-Scarlatinal Orthostatic Albuminuria.

These cases seem to suggest, not only that a scarlatinal nephritis may eventually be represented by a postural albuminuria, but that the same condition may sometimes occur after an attack of scarlet fever in which no question as to the soundness of the kidneys has been raised during the period of retention in bed, and I thought that some further information might be obtained at the fever hospital. I accordingly took the problem to Dr. E. H. R. Harries, the medical superintendent of the Birmingham Fever Hospitals, and he most kindly gave me every facility for investigating the matter. He referred me to Dr. W. M. MacFarlane, the medical superintendent of the Lodge-road Scarlet Fever Hospital, to whom I am much indebted for placing two children's wards at my disposal, as I am also to the sisters and nurses in charge of the wards for much trouble taken in procuring the necessary specimens. Dr. MacFarlane allowed me to examine a series of specimens of urine passed some three hours after getting up in the morning by a number of children convalescent from scarlet fever, none of whom had shown any sign of albuminuria so long as they had remained in bed. On the first occasion on which this was done 10 urines were collected for my examination, and of these four contained a material quantity of albumin. Three of the albuminurias proved to be fleeting; at any rate, no albumin was discovered in any of the three two days later. But the fourth gave on that day a definite response to the standing test, the bed urine being albumin-free, and an hour later a larger albuminuria had developed. This boy went home next day, the subject, for the time at all events, of a moderate postural albuminuria.

I have now examined the urines of 83 of these children, the conditions being exactly similar in each case. Of these 83 urines, 22 contained a considerable quantity of albumin on the first examination; I have omitted several others in which the amount of albumin was very small. Seven of the 22 patients went home to my knowledge with an albuminuria of the orthostatic type, found to be present on more than one occasion, and I have added to the list five others in whom discharge from hospital prevented me from making more than one examination. The rest I have discarded—three because no albumin was found on a second examination, and others because the second examination showed only a small amount. In discarding all these I am probably altogether understating my case, for a single negative or slight result is rarely safe ground for excluding an orthostatic albuminuria, but it is better to err on that side. What has especially struck me has been the unvarying regularity with which these albuminurias have been found. I paid in all nine visits to the fever hospital and examined on an average nine urines at each visit. There was not a single occasion on which I did not obtain from two to four or more positive results. As will later be stated, such results have not been obtained in examinations made in other conditions. Particulars of the cases that have not been discarded are as shown in the table following.

The slight bed albuminurias noted on single occasions in Cases 3, 4, 5, and 7 have probably the usual explanation of contamination by the albumin excreted shortly after getting to bed the night before, for in all these cases on another day, or on other days, this urine has been found to be free from albumin. Case 6, with a slight bed albuminuria, rests on a single examination, but the same explanation probably holds. It has not been possible, however, to put the explanation to the proof which I have applied to such cases in my own wards. It is further to be regretted that I have not so far been able to follow up the after-history of these cases. There are considerable difficulties in the way, but, should opportunity offer, I shall avail myself of it. It may be, of course, that some or even all of the albuminurias may have cleared up after the return home, and this gap in the evidence is unfortunate. But the results may fairly be looked at in connexion with the first and second of my recorded cases. In these an exactly comparable orthostatic albuminuria was discovered a week and a fortnight respectively after discharge from hospital, and the albuminuria is known to have persisted for at least a year in the one case and for seven years in the other.

No. of case.	—	Units of albumin in bed urine.	Units of albumin after getting up.

9	„ 12th	15	210 „
10	„ 25th	0	60 „
11	„ 25th	0	36 „
12	„ 25th	0	48 „

These cases seem to establish the fact that patients who have passed through an attack of scarlet fever without showing any albuminuria so long as they remain in bed, not infrequently develop, at any rate for a time, an orthostatic albuminuria on getting up. The interpretation remains for discussion. Four possibilities occur to me—there may be others of which I have not thought. The explanation may be one of coincidence, and all these patients may have been the subject of an orthostatic albuminuria previous to their attack of scarlet fever. Or, again, it may be that in any series of children getting up after a few weeks' illness in bed, a certain number will develop a temporary postural albuminuria—a sort of protest by the kidney against resuming work under harder conditions.

The only way of testing the truth of these suggestions is by examining a control series of children, roughly of the same age, convalescent from illnesses other than those due to specific infections. This I have attempted to do, but it has been difficult to obtain any material number of suitable cases, and for most of those that I have been able to examine I am indebted to my colleague, Dr. K. D. Wilkinson, who has found them for me at the Children's Hospital. I have now examined 35 cases and have found amongst them three instances of albuminuria of the orthostatic type. Two of these children had been in the fever hospital a few months previously with an attack of scarlet fever, and may, I think, fairly be excluded. The third had an active suppuration of the glands of the neck, and was therefore not really convalescent from her infection. If I accept this case as an example of coincidence and not the result of infection, I get a percentage of 3·1 positive results

A lad, aged 16, in whom an albuminuria had been discovered on routine examination preliminary to application for admission into the Air Force, was admitted into the Birmingham General Hospital under Dr. L. G. Parsons, to whom I am indebted for the opportunity of examining him. The albuminuria had been regarded as almost certainly of the postural variety, but a small amount of albumin had been persistently present in the night's collection of urine—he was up and about all day.] On May 2nd–3rd the following observations were made :—

	c.cm. urine.	Albumin units.
9 P.M.—On going to bed	20	375
11 P.M.—Two hours after lying down	120	18
7 A.M.—On getting up	230	0
9 A.M.—Two hours up	30	320

On this occasion the bladder was emptied afresh two hours after going to bed and the morning urine was then free from albumin. Had the 11 P.M. urine been retained, the morning specimen would have contained from 6 to 7 units of albumin, a small, but quite recognisable haze.

CHART 1.

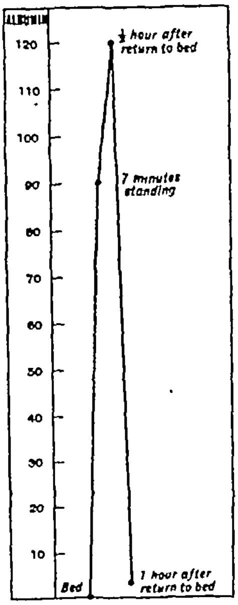

CHART 2.

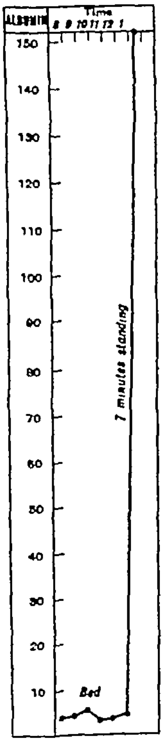

The second case was that of a girl, aged 11, who was in my ward in May, 1924, with a postural albuminuria of large degree. A year later she was readmitted for further investigation, and now the morning urine regularly contained a haze of albumin. But on April 11th, after being up all day, she went to bed with an albuminuria of 90 units, and an hour later was made to pass urine again. Next morning the night's collection was entirely free from albumin.

This source of fallacy will receive further illustration in others of my cases. It is one that is not, I think, generally recognised, but unless it is kept in mind many strictly orthostatic cases will pass undiagnosed.

(2) The second source of fallacy lies in the fact that during diuresis the upright position loses its effect on the excretion of albumin. For this reason in a suspected orthostatic case it is never safe to depend upon the absence of albumin from a single plentiful specimen of urine. And even in the absence of diuresis it must always be remembered that the sitting posture also abolishes the albuminuria.

INFECTIVE ORIGIN OF MANY CASES OF ORTHOSTATIC ALBUMINURIA.

In the paper already referred to the first case studied was that of a girl in whom the albuminuria had first been discovered immediately after an attack of diphtheria. I have now to bring forward evidence pointing to a connexion between the orthostatic condition and a past attack of scarlet fever. I am aware that the origin of the condition in a former attack of scarlatinal nephritis has often been suggested, but, as will be seen, that is not exactly my contention.

CASE 1.—I am indebted to Dr. H. Savage, my former house physician, for bringing this case to my notice, and for permission to publish the details. The patient was a girl, aged 8, who was seen by him when in practice in Coventry. Two months previously the child had been admitted into the Fever Hospital with an attack of scarlet fever, and she was discharged at the end of six weeks, without any known abnormality of the urine. A week after her return home she was brought to Dr. Savage with œdema of the left leg and the left side of the face; the urine contained a thick cloud of albumin, and casts were found in the deposit. The girl was put to bed, and the œdema and albuminuria at once came to an end. After a further period of rest in bed the œdema did not return on getting up, but from that time, whilst the bed urine was invariably free from albumin, 10 minutes' standing always produced a definite cloud. On Dec. 2nd, 1923, some four months after the onset of the fever, two specimens of urine were brought to me for examination. One, passed immediately after getting out of bed in the morning, was quite free from albumin. The other, passed soon after standing upright for 10 minutes, contained 110 units, a fairly thick cloud. On occasions, during the next 12 months, further specimens were examined with the same result, but by the end of 1924 the immediate response to standing had practically ceased. Whether or not the urine of the rest of the day was albuminous I do not know, as the case passed out of reach.

CASE 2 was that of a young man, aged 25, who contracted scarlet fever in the army in 1918. He was treated for six weeks in the Fever Hospital, and was discharged without any suspicion of renal disease. A fortnight later he was examined for some routine purpose and albumin was discovered in the urine, and eventually he was discharged from the army with the diagnosis of nephritis. From that time onwards his doctor had found an "intermittent albuminuria." He consulted me in May, 1925. The blood pressure was 85/142, but I thought that the rather high systolic reading might be partly the result of excitement. The heart was not recognisably enlarged and I could find no casts in the urinary deposit. On May 23rd he sent me a series of specimens of urine passed at hourly intervals throughout the morning, together with one passed on going to bed the night before, with the following results :—

	c.cm. urine.	Albumin units.
11 P.M.—On going to bed	42	90
8 A.M.—On getting up	300	6
9 ,,	35	70
10 ,,	46	65
11 ,,	40	70
12 noon	55	36
1 P.M.	50	28

The trace of albumin in the early morning specimen is easily explained by the fact that the urine was *heavily loaded* at bedtime the night before, and the bladder had not been emptied again during the night.

The two following cases suggest that a definite scarlatinal nephritis may ultimately be represented by a postural albuminuria.

CASE 3.—A girl, aged 13, was sent into my ward on account of an albuminuria discovered in the out-patient room. Two years previously she had had an attack of scarlet fever and her mother was informed that the kidneys were slightly affected and that the urine was "not quite right." The albuminuria was entirely postural in occurrence, though the immediate response to standing was but slight.

CASE 4 was that of a young man, aged 21, who consulted me for "nephritis." At the age of 10 he had had an attack of scarlet fever which was not at first diagnosed. In consequence he went about for some days and a nephritis developed. From that time albumin had been almost always found in the urine, and a year ago a very serious prognosis had been given. When I saw him in May, 1924, he was somewhat pale and complained of being easily tired. The heart was not enlarged and the blood pressure was 80/130. The urine passed in my room contained a cloud of albumin, but neither in this specimen nor in others subsequently examined was I able to find any casts. Next morning the *urine passed on getting out* of bed contained 8 units of albumin, and 10 minutes' standing produced a dense cloud of over 500 units. On other occasions the same trace of albumin was found in the bed urine, but that this was due to the continued excretion of albumin during the first period after getting to bed at night is shown by the fact that on one occasion when the bladder was emptied afresh an hour after lying down the urine next morning was absolutely albumin-free.

Post-Scarlatinal Orthostatic Albuminuria.

These cases seem to suggest, not only that a scarlatinal nephritis may eventually be represented by a postural albuminuria, but that the same condition may sometimes occur after an attack of scarlet fever in which no question as to the soundness of the kidneys has been raised during the period of retention in bed, and I thought that some further information might be obtained at the fever hospital. I accordingly took the problem to Dr. E. H. R. Harries, the medical superintendent of the Birmingham Fever Hospitals, and he most kindly gave me every facility for investigating the matter. He referred me to Dr. W. M. MacFarlane, the medical superintendent of the Lodge-road Scarlet Fever Hospital, to whom I am much indebted for placing two children's wards at my disposal, as I am also to the sisters and nurses in charge of the wards for much trouble taken in procuring the necessary specimens. Dr. MacFarlane allowed me to examine a series of specimens of urine passed some three hours after getting up in the morning by a number of children convalescent from scarlet fever, none of whom had shown any sign of albuminuria so long as they had remained in bed. On the first occasion on which this was done 16 urines were collected for my examination, and of these four contained a material quantity of albumin. Three of the albuminurias proved to be fleeting; at any rate, no albumin was discovered in any of the three two days later. But the fourth gave on that day a definite response to the standing test, the bed urine being albumin-free, and an hour later a larger albuminuria had developed. This boy went home next day, the subject, for the time at all events, of a moderate postural albuminuria.

I have now examined the urines of 83 of these children, the conditions being exactly similar in each case. Of these 83 urines, 22 contained a considerable quantity of albumin on the first examination; I have omitted several others in which the amount of albumin was very small. Seven of the 22 patients went home to my knowledge with an albuminuria of the orthostatic type, found to be present on more than one occasion, and I have added to the list five others in whom discharge from hospital prevented me from making more than one examination. The rest I have discarded—three because no albumin was found on a second examination, and others because the second examination showed only a small amount. In discarding all these I am probably altogether understating my case, for a single negative or slight result is rarely safe ground for excluding an orthostatic albuminuria, but it is better to err on that side. What has especially struck me has been the unvarying regularity with which these albuminurias have been found. I paid in all nine visits to the fever hospital and examined on an average nine urines at each visit. There was not a single occasion on which I did not obtain from two to four or more positive results. As will later be stated, such results have not been obtained in examinations made in other conditions. Particulars of the cases that have not been discarded are as shown in the table following.

The slight bed albuminurias noted on single occasions in Cases 3, 4, 5, and 7 have probably the usual explanation of contamination by the albumin excreted shortly after getting to bed the night before, for in all these cases on another day, or on other days, this urine has been found to be free from albumin. Case 9, with a slight bed albuminuria, rests on a single examination, but the same explanation probably holds. It has not been possible, however, to put the explanation to the proof which I have applied to such cases in my own wards. It is further to be regretted that I have not so far been able to follow up the after-history of these cases. There are considerable difficulties in the way, but, should opportunity offer, I shall avail myself of it. It may be, of course, that some or even all of the albuminurias may have cleared up after the return home, and this gap in the evidence is unfortunate. But the results may fairly be looked at in connexion with the first and second of my recorded cases. In these an exactly comparable orthostatic albuminuria was discovered a week and a fortnight respectively after discharge from hospital, and the albuminuria is known to have persisted for at least a year in the one case and for seven years in the other.

5	June 28th July 6th „ 12th „ 19th	0 0 7 0	130 „ 110 „ 93 „ 100 „
6	June 28th July 7th	— 0	180 2 hours up. 65 3 hours up.
7	„ 12th „ 19th	9 0	120 „ 7 „ (Urine plentiful).
8	„ 12th	0	300 3 hours up.
9	„ 12th	15	210 „
10	„ 25th	0	60 „
11	„ 25th	0	30 „
12	„ 25th	0	48 „

These cases seem to establish the fact that patients who have passed through an attack of scarlet fever without showing any albuminuria so long as they remain in bed, not infrequently develop, at any rate for a time, an orthostatic albuminuria on getting up. The interpretation remains for discussion. Four possibilities occur to me—there may be others of which I have not thought. The explanation may be one of coincidence, and all these patients may have been the subject of an orthostatic albuminuria previous to their attack of scarlet fever. Or, again, it may be that in any series of children getting up after a few weeks' illness in bed, a certain number will develop a temporary postural albuminuria—a sort of protest by the kidney against resuming work under harder conditions.

The only way of testing the truth of these suggestions is by examining a control series of children, roughly of the same age, convalescent from illnesses other than those due to specific infections. This I have attempted to do, but it has been difficult to obtain any material number of suitable cases, and for most of those that I have been able to examine I am indebted to my colleague, Dr. K. D. Wilkinson, who has found them for me at the Children's Hospital. I have now examined 85 cases and have found amongst them three instances of albuminuria of the orthostatic type. Two of these children had been in the fever hospital a few months previously with an attack of scarlet fever, and may, I think, fairly be excluded. The third had an active suppuration of the glands of the neck, and was therefore not really convalescent from her infection. If I accept this case as an example of coincidence and not the result of infection, I get a percentage of 3·1 positive results amongst these children, as compared with one of 26·5 amongst similar single examinations made in the convalescent scarlet fever cases. If I give the decision wholly, and, I think, wrongly against myself, and include the two children who had recently been discharged from the fever hospital, the percentage is 8·6 against 26·5. I do not think, therefore, that either of the above suggestions will account for my results. I suppose that a third explanation might lie in some obscure vaso-motor effect of the scarlatina. But such an explanation seems too vague for serious discussion, unless one starts out with the assumption that orthostatic albuminuria must necessarily be functional in nature, and it is this assumption that I am combating.

The only other explanation that I can see is one that falls in with the impression that has gradually grown up in my mind as the result of a long study of the orthostatic reaction—namely, that this type of albuminuria is in many cases the expression of a past renal infection of mild degree, and the suggestion would then be that in these post-scarlatinal postural albuminurias we are meeting with the very smallest degree of infection of the kidney. The conception of an infection so slight that it never translates itself into an albuminuria so long as the patients are kept in the horizontal position may seem far-fetched, but I can see no inherent impossibility in the idea. It postulates a damage to the kidney far short of anything so far described in the post-mortem room, but such degrees of damage must surely exist. Whatever the explanation, the facts are as I have stated them.

My results raise a further question—namely, whether it is not possible that cases of orthostatic albuminuria, with no known history of scarlet fever, may yet have had a scarlatinal origin. Dr. Harries tells me that in his opinion many cases of scarlatinal infection probably pass unrecognised as an "ordinary" sore-throat without rash. If that is so, the absence of a history of scarlet fever in genuine post-scarlatinal orthostatic cases would be easy to understand. We are accustomed to speak of the "adolescent type" of albuminuria, as though it were only to be expected that the adolescent kidney should at times leak albumin. I see no reason why the adolescent kidney should behave in this manner, but I do recognise that childhood and adolescence are the periods of special susceptibility to specific infections.

THE CONNEXION BETWEEN ORTHOSTATIC ALBUMINURIA AND PREVIOUS SCARLATINAL NEPHRITIS.

The connexion between orthostatic albuminuria and a past attack of scarlatinal nephritis has been previously suggested. Bass,[1] in 1912, gave an abstract of three papers dealing with the subject. Weiss-Eder[2] allowed 40 children with scarlet fever to kneel in a position of lordosis, with the result that 28 developed an albuminuria. The writer concludes that children convalescent from scarlet fever are not more disposed to nephritis than other children, and that such children, having nephritis, often show an orthostatic albuminuria, "which may be due to weak muscles." Nothman[3] found that 12 out of 13 cases of scarlet fever in which at an earlier date the lordotic experiment was positive, albumin appeared later in the urine, but that in those in which lordosis did not cause albuminuria, albumin never appeared spontaneously later on. He concludes that, just as nephritis may terminate in orthostatic albuminuria, so conversely an orthostatic albuminuria may be the first sign of nephritis. Schick[4] says that orthostatic albuminuria following scarlet fever has a good prognosis, and refers to Jehle, who examined 17 children in various stages of scarlet fever. In 12 there occurred a marked albuminuria in the position of lordosis, upright and prone, but none developed a nephritis. In each case I quote from Bass's abstract.

On the other hand, Hansborg,[5] of the Blegsdam Fever Hospital, Copenhagen, after a very careful study of the after-history of a large number of patients who had suffered from scarlatinal nephritis, rejects the idea that there is any special connexion between such nephritis and the subsequent development of orthostatic albuminuria. Among 226 children and young people, who had all had scarlatinal nephritis, he found 23 (10 per cent.) with orthostatic albuminuria, "which is even a lower figure than is generally quoted in examinations of arbitrarily chosen individuals of the same age" (I quote from a translation). I gather, therefore, that Hansborg looks upon these patients as likely to have been the subjects of an orthostatic albuminuria previous to their attack of scarlet fever. While holding that no single explanation hitherto propounded accounts alone for the condition, he supports the usual view that lordosis plays, at any rate, a chief part in its causation, though he admits that in only 6 of his 23 cases was a "pathological" lordosis to be discovered. But, he adds, "what can be considered as pathological here must be *a matter* of expert opinion."

While it is desirable to include a reference to these various opinions, it is to be noted that they largely deal with two matters with which my paper is not particularly concerned—namely, the occurrence of orthostatic albuminuria as the result of scarlatinal nephritis, and the effect of artificial lordosis in patients convalescent from scarlet fever. My point is that this type of albuminuria appears to develop on getting up in patients who have not shown any sign of nephritis during rest in bed, and for this it has not been necessary to assume any position of lordosis, which, after all, is only the extreme of the upright position. That lordosis is the essential cause of orthostatic albuminuria I do not believe. The evidence in its favour has never seemed to me very conclusive, and so many of my cases have shown an absence of material lordosis on X ray examination that I have long discarded it as an adequate explanation. Hansborg's cases, again, hardly seem to afford it much support. It may be, however, that there is a type of case into the causation of which it enters, as suggested at the end of my paper.

INFECTIONS OTHER THAN SCARLATINAL.

I come now to infections other than scarlatinal. I have already alluded to a case in which the condition was discovered immediately after an attack of diphtheria, and Dr. Chalmers, of the Little Bromwich Fever Hospital, very kindly collected for me one day the urines of 18 children convalescent from diphtheria; out of over 300 cases then in hospital these were the only ones in which no albumin had been discovered during the bed period. The children had all been up three hours, and the urines were therefore strictly comparable to those of the scarlet fever series. In these 18 urines I found one with a big albuminuria (560 units) in the upright specimen, the bed urine being albumin-free. One other urine showed a trace of albumin comparable to those discarded in the scarlet fever cases. These observations are again opposed to the explanation of the post-scarlatinal orthostatic albuminurias on the ground of coincidence. I know of a man, 49 years of age, with a postural albuminuria who dated his condition from an attack of syphilis occurring many years previously, and I have come across the case of a woman with an albuminuria of the same type who had had eclampsia two years ago. But both of these cases rest on a single examination only, and I cannot attach any great importance to them. Lastly, I have under observation two boys who were in my ward with a mild attack of acute nephritis of ordinary type, and who left hospital with a bed urine that was almost free from albumin and a big upright albuminuria. They were readmitted for 24 hours, three and two years respectively after their acute attack. In one the bed urine was nearly, but not quite, free from albumin; in the other no trace of albumin was found in the bed specimen. Both developed a large albuminuria immediately on getting up. While, therefore, I think that there is a special tendency for orthostatic albuminuria to develop, at any rate for a time, in patients getting up after an attack of scarlet fever, I am far from holding that the reaction is specific to that infection.

[5] Acta Medica Scandinavica, Feb. 12th, 1925.

Two further points have impressed me as possibly bearing on the question of the infective origin of orthostatic albuminuria. The first is the frequency with which cases come under notice on account of symptoms of ill-health. A certain number of my cases have been discovered on routine examination for some purpose or other, but the majority have come complaining of headache, fatigue, lassitude, and occasionally some little swelling of the face. With a few days' rest in bed these symptoms have disappeared or a slow improvement has taken place. Secondly, it not uncommonly happens that a case in which such symptoms are present on admission shows at first an exaggerated response to the upright position, which also diminishes with rest in bed. For example, a boy, aged 13, was admitted from the out-patient room complaining of general ill-health. On Nov. 20th, 1924, seven minutes' standing gave rise to an enormous albuminuria (650 units), whilst on Dec. 1st eight successive hourly specimens passed in bed were all entirely free from albumin. A fortnight later he was up with quite a moderate albuminuria—a maximum of 40 and 50 units, whilst standing now produced but a small response. But I would add that the variations in the response to the upright position in these cases are often so extraordinary that I must not attach too much importance to an apparent improvement such as is shown in this case. It may be that a few more observations would have upset the conclusion, and I have one case in mind in which a similar apparent improvement was suddenly reversed during the patient's stay in hospital.

RELATIVE PROPORTIONS OF GLOBULIN AND ALBUMIN.

I may briefly refer to the question of the preponderance of globulin over albumin in the urine, almost universally accepted as marking off the orthostatic cases from those of albuminuria of organic origin. My experience does not support the distinction. Certainly, if it holds, the organic nature of most of my cases of orthostatic albuminuria is definitely proved, but the relationship seems to me altogether too variable for use in diagnosis. I am far from denying that in the great majority of cases of nephritis albumin is enormously in excess of globulin, but I have come across a few cases of definite acute nephritis in children in which the reverse relationship has been present. On the other hand, of 11 apparently non-scarlatinal cases of orthostatic albuminuria in which I have kept notes on the point, in four globulin was in excess, and in the remaining seven a big excess of albumin was registered. In the scarlatinal cases examined at the fever hospital the same inconstancy of relation was noted. Two of the urines showed an undoubted excess of globulin, but in most of the others there was an equally undoubted preponderance of albumin. I did not, however, remember in every case to make the necessary observations. Each of the two positive diphtheritic cases showed an excess of globulin.

POSTURAL ALBUMINURIA A SYMPTOM.

I began by stating that I would regard postural albuminuria as a symptom only, and that the limitation of the term to the cases in which the bed urine is entirely free from albumin, convenient as it may be, tends to rob the symptom of much of its significance. The fact is that in many, and possibly all, forms of albuminuria the albumin output is susceptible to the influence of posture, though in very varying degrees in different cases. This is, I think, certainly true of the "parenchymatous" varieties of nephritis, acute and chronic, and several of the charts published in the *Quarterly Journal* show an albuminuria in mild acute nephritis which came down to a very small amount with the patient in bed, but was present in gross quantity in the upright position. I would therefore regard the complete cessation of albumin excretion in the horizontal position, characteristic of "orthostatic albuminuria," merely as the extreme example of the influence of posture. The following records are taken from the case of a man with chronic nephritis, a somewhat raised blood pressure, and numerous casts in the urine:—

	Albumin units.
On going to bed..	1100
One hour after going to bed ..	120 (urine plentiful)
On getting up next morning ..	530 (urine concentrated)
Three hours after getting up ..	700
Seven hours after getting up ..	1275

The very big drop in albumin content an hour after going to bed is to be somewhat discounted by the fact that during the hour a plentiful urine was secreted, and, on the other hand, the relatively high morning reading is largely accounted for by the concentration of the urine of the rest of the night, due, of course, to the absence of fluid intake. But the influence of posture seems undeniable. Whether this influence is exerted in the chronic interstitial types of nephritis I am not so certain, but this is a matter which I have not carefully investigated.

Finally, cases are met with in which the albuminuria is almost, but not quite, "orthostatic" in nature, and these seem to me to form a possible connecting link between the completely orthostatic cases and cases of nephritis responsive to posture. Chart 2 (p. 681) gives an example of such a case. The patient, a boy aged 14, was in fairly good health when one day he fainted at school. Examination of the urine showed a large cloud of albumin, and he was put to bed, with the result that the albuminuria at once very nearly came to an end, but never quite ceased. When I saw him he had been in bed for some weeks. The blood pressure was a shade high for the age (130, systolic), but no casts were at any time found in the urine. As shown in the chart (one record out of many is alone included), he was intensely sensitive to the upright position, and seven minutes' standing always produced a big response. When he got up in the morning a very large albuminuria developed, but getting up in the afternoon gave a much smaller result—an approach to the "cyclical variation." Yet the bed urine invariably showed a slight albuminuria. It is difficult, I think, on this ground to separate the case from the more complete forms of postural albuminuria.

I do not claim that all cases of orthostatic albuminuria have the same or a similar origin. I believe that cases exist in which the symptom is due to mechanical embarrassment, possibly of the left renal vein, and in THE LANCET of Oct. 27th, 1923, I have myself recorded a case of unilateral oedema with an albuminuria probably coming from one kidney only, for which I suggested a purely mechanical explanation. Will it eventually be found that the cases of mechanical origin are those in which the albumin comes from one kidney only? A certain number of cases of orthostatic albuminuria have been recorded in which catheterisation of the ureters has demonstrated that this was the case. I have some suspicion that these may prove to be the really "functional" cases, and that they own a totally different pathology from that of the cases dealt with in this paper. It may be that here lordosis is of importance. I may add that in five of my orthostatic cases I have tried by postural experiments—standing leaning first to one side and then to the other—to obtain evidence of the unilateral origin of the albuminuria, but in none has there been any material difference in the results.

SUMMARY AND CONCLUSIONS.

1. Many patients suffering from scarlet fever, who present no albuminuria during the period of rest in bed, develop an orthostatic albuminuria immediately after getting up. Some, at any rate, of these albuminurias persist for a considerable time, or even permanently.

2. Some cases of recognised scarlatinal nephritis are ultimately represented by an albuminuria of the orthostatic type.
3. Orthostatic albuminuria may follow other forms of specific infection, or even, though rarely, arise as the end-result of a mild acute nephritis of ordinary type.
4. The proportions of serum globulin and serum albumin are not constant in cases either of orthostatic or nephritic albuminuria, and do not enable a differential diagnosis to be made.
5. It is suggested that in many cases the orthostatic reaction is the result of slight renal damage. But cases probably exist in which the reaction is the result of mechanical causes. As a matter of speculation, it is suggested that in these cases the albumin comes from one kidney only.
6. Some response to posture occurs in most cases of nephritis, and possibly in all forms of albuminuria. All degrees of diminution of the output of albumin during rest in bed are met with, down to the complete cessation of the typical orthostatic cases.
7. Orthostatic albuminuria is probably of more frequent occurrence than is generally supposed. It may pass unrecognised owing to (1) the presence of a small quantity of albumin in the morning specimen of urine, due to the continuance of the upright albuminuria for half an hour or so after going to bed the night before, and the consequent contamination of the night's collection; (2) the cessation of albumin excretion during diuresis, even in the upright position; and (3) the cessation of albumin excretion in the sitting position. Extreme variations in the albumin output, with at times complete cessation, are therefore to be expected.

An Address

ON THE

CURES OF ÆSCULAPIUS.

Delivered to the Students of Westminster Hospital at the Opening of the Winter Session

BY PROF. ERNEST A. GARDNER, LITT. D.,
VICE-CHANCELLOR OF THE UNIVERSITY OF LONDON.

AN interesting chapter in the history of ancient medicine is offered by the cures of Æsculapius, or Asclepios, as the Greeks called him; and the subject is one upon which the students of medicine and archæology meet upon common ground. It has been much discussed whether the priests and descendants of Asclepios, the Asclepiadæ, were the depositories of a traditional skill in medicine and surgery; and in this connexion we must remember that Hippocrates himself was one of the Asclepiadæ, of Cos. The remains of an enormous plane tree in the market-place of the town are still shown to visitors as the place where he gave consultations to his patients. The sacred precinct of Asclepios at Cos is situated in a delightful position on a terrace overlooking the sea, and there it is still possible to trace the remains not only of temples and altars, but also of the rows of cells which must have served as quarters for the invalids who came to consult the god or his attendants. Many such shrines of Asclepios existed upon various sites in ancient Greece, most of them in similar positions and surroundings. But two of these are of especial interest to us because we have actual records in literature and inscriptions of the method of consulting the god and the means by which cures were effected. These two are at Athens, where the precinct underneath the south side of the Acropolis referred to by Aristophanes may still be seen; and at Epidaurus, where there have been found not only the remains of the buildings, but two of the six great slabs mentioned by the traveller Pausanias as recording the cures effected by the god.

These two precincts of Asclepios were very similar in their arrangement, though that at Epidaurus was by far the more extensive. Both alike containe more than one temple and one great altar of sacrifice as well as springs or sacred wells. But the mos distinctive building in each was a large portico in tw floors, partly closed and partly open to the air, an it was in this building, called in inscriptions th "abaton," that patients who came to be cured spen the night. How they spent it may be partly judge from the well-known description in the Plutus o Aristophanes; for though this description is o course burlesque, and may well appear lacking i reverence, it must have had sufficient resemblance t what actually took place to give point to the jests In the play Plutus (Wealth) is represented as blind and his friends resolve to take him to the shrine o Asclepios in Athens "to help him of his blindness.' The slave Karion, who attends him during his visit gives a full account of it, which may be summarised a follows:—

> "First we took him to the sacred spring and washed him then we entered the precinct of the god, and after offerin cakes and the other preliminary sacrifices, we duly put hir to bed, among a number of others suffering from diver diseases, and we ourselves had shakedowns beside him Then a minister of the god came in and put out the light and bade us go to sleep, and keep silent if we heard any sound. So we all lay quiet. But I could not get to sleep and I saw the priest going round the sacred tables and altars, picking up the figs and cakes and consecrating them into a bag. Then the god appeared, accompanied by his two attendant maidens, Iaso and Panacea. I hid my head under my cloak in fear, but I watched through the holes in it. And I saw the god going the round of the cases in due order, and an acolyte set beside him a stone pestle and mortar and a medicine chest. He first approached Neoclides, a blind man who excels those who can see at thieving, and he mixed and ground an ointment for him of garlic and fig-juice and squills with vinegar, and anointed his eyelids, turning them back to increase the smart. And the patient shrieked and cried out and tried to run away; but the god laughed and told him to sit still with his plaster. Then he came to Plutus and sat beside him, and first he felt his head, then he took a clean napkin and wiped his eyelids; and Panacea covered his head and face with a purple cloth. Then the god whistled, and two enormous snakes issued from the temple and gently crept under the cloth, and as it seemed to me, licked round his eyelids; and immediately Plutus stood up with his sight restored; and I clapped my hands for joy, and the god vanished with his snakes into the temple. And those who were lying beside Plutus congratulated him and remained awake all night till dawn."

Here we see many of the incidents that are repeated in the records of the cures at Epidaurus; but there is some confusion in both cases as to what actually took place and what was seen in a vision or a dream. But in the Plutus it seems distinctly to be suggested that the priest of Asclepios actually personated the god, a custom not at all unusual in Greek religion; and we know from other sources that large snakes were usually kept in the shrines of Asclepios, and were even in some cases regarded as the god himself.

ANCIENT GREEK RECORDS.

Before proceeding to enumerate the cures recorded at Epidaurus, a few words must be said as to the documents on which they are recorded. These are large slabs of marble headed "Cures of Apollo and Asclepios," discovered and first edited by M. Cavvadias, the Greek Inspector-General of Antiquities. Among medical authorities who have written about them, I would especially mention Sir Clifford Allbutt, Dr. Caton, and Dr. Alexander Cavvadias, son of their discoverer. The slabs were inscribed some time about 300 B.C., but they cannot be regarded as contemporary records of cures. They were evidently compiled at one time, and as we shall see, the source from which they were derived was partly the votive offerings with inscriptions that had been set up by the patients to testify their gratitude to the god, and partly the traditions of the temple; and the fact that one of the most curious cases is recorded by a Greek writer of nearly 200 years earlier in a slightly different form shows that this temple tradition did not deal only with recent cures. Such stories doubtless improved by repetition. Whether some of them had a basis of fact or not is a matter as to which I express no opinion. But, in a general way, many of them seem to have similar essential features, and to agree with the description given by Aristophanes. In nearly all cases the patient comes to the shrine of Asclepios, sleeps in the "abaton," has a vision or a dream, in which some action is taken by snakes or dogs, or else something similar happens to him while he is awake; and as a result he goes forth whole in the morning. Naturally, cases that are not so cured are not recorded, except in instances where the god showed his divine power by punishing an unworthy worshipper—just as in the Plutus happened to the thief Neoclides.

I now proceed to cite a selection from the cases, without any attempt at classification, in the order in which they are recorded on the slabs.

1. Cleo was with child for five years, and in the fifth she came to the god as suppliant and slept in the abaton; and immediately on leaving it and going outside the precinct, she gave birth to a male child, who directly he was born washed himself with water from the sacred spring and went about with his mother. And Cleo, being thus favoured, inscribed on her dedication: "It is not the size of the picture (or relief) that is wonderful but the divine power, since Cleo was pregnant and bore the burden in her womb for five years, until she slept in the sanctuary and the god made her whole."

This is important as evidence, for Cleo's inscription probably existed, and the rest of the tale may well have been made up to explain it. Possibly Cleo and the child were represented in the picture or relief, and a later generation might not understand the custom in early art of representing young babies as much too mature in form.

2. A man with all his fingers but one paralysed came as a suppliant to the god, and seeing the pictures in the precinct he disbelieved the cures and jeered at the inscriptions. He slept in the abaton and saw a vision. He seemed to be playing knucklebones in the precinct, and the god appeared and seized on his hand and stretched out his fingers. And when he went out he fancied he clenched his hand and stretched out his fingers one by one. And when they were all straightened the god asked him if he still disbelieved. He said no, and the god advised him to distrust his scepticism in future. And when day came, he went out whole.

3. Ambrosia of Athens, with one eye, having come as a suppliant to the god, went round and ridiculed some of the cures, saying it was improbable or impossible that the lame and the blind could be cured merely by seeing a dream. She slept in the abaton, and saw a vision. She thought the god stood by her and said he would cure her, but as his fee she must dedicate in the precinct a silver pig as a reminder of her stupidity. And then he cut open her diseased eye and poured some drug into it; and when day came she went out whole.

Here again we have an indication of the source of the story. The pig was doubtless on show, and the true explanation may be quite different.

4. A dumb boy came as a suppliant for speech, and made the preliminary sacrifice; then the acolyte of the god said, looking at the boy's father "Do you promise within a year, if he gets his wish, to pay the fee?" And the boy suddenly said "I promise." His father was astonished, and bade him repeat it; he did, and was cured from that moment.

This is a case which is, I believe, easily paralleled from modern experience. The next two are evidently edited with a purpose. I summarise them briefly:—

5. Pandaros had certain spots on his forehead. The god appeared to him in a dream, and put a bandage on them, bidding him on leaving to dedicate the bandage. When day came he took off the bandage and dedicated it in the temple, and his spots were gone. Echedorus, who suffered from the same complaint, came with a sum of money from Pandaros to dedicate to the god. He saw a vision in a dream. He thought the god asked him about this money, and he denied it, but promised to dedicate a picture if he were cured. The god put Pandaros' bandage on his forehead, and bade him when he went out to wash his face from the sacred spring, and look in the water. He did so, and saw that Pandaros' spots were added to his own previous ones.

6. This case is of a boy suffering from stone. He thought the god stood by him and said: "What will you give me if I cure you?" and he said "Ten knucklebones." The god smiled and said he would cure him; and when it was day he went out whole.

7. A man came to the god as a suppliant so blind in one eye that only the empty socket was left; some pointed out his folly in thinking he could come to see when there was no eye there. He slept and saw a vision; he thought the god mixed a salve and opened his eyelids and poured it in; and when day came he went out seeing with both eyes.

Here a comparatively common case seems to have been improved by the priests to increase the wonder of the cure. The next is a quaint story, not medical at all, but apparently intended to show the general powers of the god.

8. A porter fell down more than a mile from the precinct, and found some vases in his satchel were broken, including a cup his master used to drink from. He was distressed and sat down trying to piece together the fragments. A stranger passing by said, "That is no use, not even Asclepios could make that cup whole." He went on to the precinct, and when he opened his satchel he found the cup whole. He told the tale to his master, who dedicated the cup to the god.

I fear I can offer no explanation of this story, which shows we must admit some items to be pure invention. But doubtless the dedicated cup was on view to convince sceptics. Another case shows a human touch which reminds us of an incident in the Acts of the Apostles.

9. Æschines, when the patients were sleeping in the abaton, climbed a tree to look into it. He fell, and struck his eyes on some stakes. He was blinded, but he became a suppliant to the god, slept in the abaton and was made whole.

The next case looks like a simple example of surgery, possibly improved in detail, especially as to the quickness of recovery.

10. Euhippus carried a spear-head in his jaw six years. While he slept in the abaton the god took out the spear-head and placed it in his hands. And when day came he went out whole with the spear-head in his hands.

11. A man of Torone suffering from leeches slept in the abaton and saw a vision. He thought the god cut open his chest with a knife, took out the leeches and placed them in his hand, and sewed up his chest again. And when day came he went forth with the creatures in his hand and was made whole. He had swallowed them in a potion given him craftily by his step-mother.

12. Hermodikos was paralysed. When he slept in the abaton the god cured him and bade him when he went out to carry the biggest stone he could into the precinct, and he brought the stone that now lies in front of the abaton.

Here again the visible stone may have suggested the story.

13. Nikanor, a lame man, was seated; and a boy while he was awake stole his staff and ran away. He jumped up and pursued the boy, and from that time he was cured.

14. A man had his toe healed by a snake. Suffering greatly in his toe from a malignant wound, he was brought in the daytime by his attendants and sat down on a bench. He fell asleep, and a snake coming out of the abaton cured his toe with its tongue, and then went back into the abaton. When he awoke and found himself well he said he had seen a vision. He thought a beautiful youth applied some medicine to his toe.

This last reminds us of the cure of Plutus in Aristophanes; it is also interesting from the curious correlation of the vision in a dream with what actually happened; a confusion of the two may explain other cases. A belief in the healing power of the snake is of course common enough.

15. Alcetas, being blind, saw in a dream the god approach him and open his eyes with his fingers, and he saw the trees in the precinct. And when it was day he went forth whole.

This curiously reminds one of the blind man in the Bible, who saw "Men as trees walking."

16. Heræus had no hair on his head and a bushy beard; ashamed of being a laughing-stock to others he slept in the abaton and the god anointed his head with a preparation that made his hair grow.

It is to be noted it is not stated in this case that the cure was instantaneous.

17. Thyson, a blind boy, was licked on the eyes while awake by one of the dogs in the precinct, and went forth whole.

Here there is no vision or dream, as in the case of the man cured by a snake. Dogs also are commonly reputed to have this healing power, possibly because they lick their own wounds. Sacred dogs and snakes were evidently kept in the precinct for the purpose

I have given a practically complete version of this inscription because I think the form and details of the cures quoted are of importance in forming any just estimate of the value of the record. The other slab is not so well preserved, and the records of many of the cases are only fragmentary. I do not therefore propose to reproduce them in detail; in general character they are similar to those on the first slab. But two or three of the cases are of a special interest, and I add them in summary form.

18. The mother of a girl at Sparta consulted the god on behalf of her dropsical daughter. She dreamt that the god cut off her daughter's head and hung her body neck down; when much liquid ran out, he sewed the head on again. She returned to Sparta and found her daughter, who had had the same dream, restored to health.

This kind of vicarious incubation is unusual.

19. A somewhat similar case is that of Aristagora who had a worm in her intestines. She slept in the shrine of Asclepios at Troezen, and had a dream. She thought the sons of the god, who was himself away at Epidaurus, cut off her head, and being unable to replace it, sent for the god. Meanwhile day came, and the priest saw the head separate from the body. The following night she had again a dream that the god came and replaced her head, and then cut open her abdomen, removed the worm, and sewed her up again.

Here there is obvious confusion between dream and reality, and the priest, seeing head and body apart, seems to be a corroborative detail. But the chief interest in this case lies in the fact that the same story, with some variation, is told by a writer some two centuries earlier than the inscriptions, Hippys of Rhegium. According to his version, the lady came to the precinct of Asclepios at Epidaurus, not the one at Troezen; the temple attendants attempted the cure, cut off her head, removed a gigantic worm, and then could not put the head on again. The god came and blamed them for their presumption, and put things right. It is evident that the priests would not tolerate a record of such blundering in their own temple. One or two other cases have features of interest.

20. A man having what is described as a wound or sore in his belly was lashed down when he resisted operation. Asclepios cut open his abdomen, removed the sore, and sewed him up again. He was cured, and the floor in the abaton was covered with blood.

21. A man suffering from headaches dreamt that the god gave him some training for the pancration; he was cured, and soon after won the pancration at the Nemean games.

22. Finally, a lady suffering from indigestion dreamt that the god gave her some medicine in a cup to drink which made her sick, so as to fill her basin. And when day came there was her basin full of vomit, and she was cured.

In this last case the dream seems to correspond with the fact.

These inscriptions have been much discussed, and some think them a mere tissue of superstitions and absurdities. But so high an authority as the late Sir Clifford Allbutt says that—

> "by pomp, splendour, and ancient enchantments the senses were captured, and the springs of nervous energy unsealed. . . . It is supposed that mesmerism was a potent means in the hands of the priesthood; that patients were subjected to hypnotic suggestion we know with some fulness."

I am not, of course, competent to criticise the evidence from a medical point of view, but I have studied both the records and the psychology of the ancient Greeks, and I think that, allowing for some improvement in editing on the part of the priests, above all of some confusion of dreams and facts, many of the cases above may be attributed either to medical or surgical skill, and that among them are also cases of faith-healing or of sudden impulse or suggestion due to nervous excitement. However this may be, the priests of Asclepios certainly changed their practices in later times, and seem to have taken to running sanatoria and no longer depending on instantaneous cures, for which faith no longer was forthcoming. A good example of this later treatment is offered by the case of M. Julius Apelles, in the second century A.D., who suffered from chronic dyspepsia, and was ordered by the god to take a kind of rest cure, with prescribed diet and regular exercise. Such prescriptions are not uncommon, and show that the various shrines of Asclepios had become centres of medical and even surgical therapeutics.

INCUBATION SHRINES.

Asclepios was not the only god or hero in whose shrines the custom of incubation was prevalent. In the precinct of Amphiaraus at Oropus it was customary for invalids who consulted what was practically a dream oracle to cast gold and silver coins into the sacred spring. They sacrificed a ram, and slept on its skin in the temple or a portico attached to it; they then related their dreams to the priests, who gave expert interpretations. We have unfortunately no information as to what these were like, but they may have given opportunity for medical advice. The shrine was a popular one, and therefore must have met with some success.

In another shrine, that of Trophonius at Lebadea, there were elaborate arrangements which seem to imply some mechanical devices and trickery. The traveller Pausanias, who himself went through the process, gives an elaborate description of it. After some days of preparation, with sacrifices, special diet, and cold baths, on the night chosen the patient was bathed in the river, led to the two springs of Forgetfulness and Memory, of which he had to drink, and then he descended by a ladder into an artificially constructed hole in the ground. Here he lay down with his feet up to the knees in a hole at the side. His whole body was immediately drawn through the hole by an irresistible force; the oracular response was either by sight or hearing, and he returned again through the hole feet first. The priests took him, placed him on the seat of Memory, and interrogated him as to what he had seen or heard, and then returned him to his friends, in a state of terror and unconscious of his surroundings. But he soon recovered and laughter returned to him. The priests, here also, gave expert interpretations of the sounds or visions. The oracle was mostly, though not exclusively, consulted by invalids, to whom it must have been a sore trial, though Pausanias declares none of them were ever killed by it, except a soldier who went in hope of loot, and whose body was found some distance away.

Shrines for incubation are by no means extinct in Greek lands at the present day. In conclusion, I should like to describe one of those which I have myself more than once visited. The great church and precinct of the Panagia (Our Lady of the Annunciation) in the island of Tenos is visited at her annual festival by crowds of people from all Greek lands, bringing with them many men and women suffering from all sorts of diseases, especially the blind, the lame, and the paralysed. These are laid, in their beds, on the floor of the church and of the crypt beneath it, which they fill, so that there is barely room to pass along between them. The sight must be very like the abaton in the precinct of Asclepios in old times. The patients are placed here on the eve of the Annunciation, and so spend the night. Every year some two or three so-called miraculous cures take place; one year when I was there a woman who had crawled painfully up to the church with paralysed limbs threw away her crutches and danced back to the harbour amid the rejoicings and congratulations of her friends. I do not think that fraud or collusion plays any considerable part in such cases. It is to be remembered that only two or three out of hundreds are so cured; and those who are not so forget their own state in rejoicing at the healing of another, just as the rest of the patients surrounded Plutus in the play. The many are forgotten, and the few are remembered and recorded. The case of Lourdes is, of course, similar, and I believe nobody now doubts the instances of faith-healing that have occurred there, especially in nervous or hysterical cases. A certain number of such cases, together with some examples of successful surgery or medical treatment, may well form the nucleus around which the sometimes fanciful records of the cures of Asclepios have accumulated.

An Address

ON

THE HUMAN TOUCH IN PROFESSIONAL LIFE.

Delivered to the Students of Guy's Hospital at the Opening of the Winter Session

BY MAJOR J. H. BEITH, C.B.E., M.C.

"IAN HAY."

GENTLEMEN,—First of all let me say how greatly honoured I am by your invitation to me to address you this afternoon. My pleasure, however, is somewhat diluted by the fact that I am not in any way qualified to address a medical audience—except to this extent, perhaps, that once, long ago at Cambridge, I took a course of chemistry and physics, as a sort of antidote to a prolonged dose of the classics; and also, because during those far-off undergraduate days my circle of acquaintance lay very largely among gentlemen who *kept a human skull* on the mantelpiece and a skeleton, or portions thereof, in the cupboard, and whose soaring spirits only drooped—and *that for a* moment—when their thoughts turned towards a mysterious and awful ordeal which lay waiting for them about the end of their third year, called the Second Part of the Second M.B. Moreover, it was in that noble company that I first *made* the acquaintance of my friend—your friend—our friend—Dr. H. C. Cameron, through whose offices, good or bad, I find *myself* here this afternoon.

We were a band of brothers in those days, with all things in common. Some of us were studying classics, some mathematics, some theology, some medicine, and some, of course, were merely hoping to be excused the General, or be allowed an ægrotat in botany; but just as you can distinguish the voice of the saxophone above all the other *instruments in a jazz* band, so medical interests and medical shop overtopped everything else. If one of our medical friends performed the *feat* of "passing his bones," we celebrated the event together, theological students and all. I became well versed in the airy chatter and gossip of what were called in those days, and I suppose are still called, the meat shops; and I shall never forget the scene of enthusiasm which occurred one evening, the first evening of term, when an excited second year man—one of those busy persons who are always full *of* what we will call, not inappropriately, inside stuff—burst into my room, where I was entertaining a few medical friends, seized Cameron by the *hand*, shook it warmly, and said to him: "Congratulations, old man! You've got a head and neck!" It is upon such *slender foundations* as these that I am endeavouring to build up sufficient courage to address you this afternoon.

PERSONALITY AND TRAINING.

I have labelled my discourse the Human Touch in Professional Life, by which I mean character, or personality, as compared with technical knowledge and ability. Of course, the one must not be regarded as a substitute for the other. No force of character, no attractiveness of personality in the world, can ever compensate for ignorance of one's job—in your profession of all professions. Personality is a useful, and sometimes invaluable, appendage to a man's professional equipment, but it can never constitute an equipment in itself.

I *emphasise* this rather patent fact because there is a general and dangerous tendency in the world to-day to exploit this *personality* stunt to an absurd degree, to the neglect and detriment of real training and thorough knowledge. In other words, we live in an age of advertisement—in an age, that is, where people are tending more and more to expend their energies, not upon putting quality into their goods, but upon thinking out ingenious and profitable methods of disposing of those goods. The theory appears to be that if you advertise them long enough and loud enough it does not matter whether your goods are good or not. So the art of advertising has now been elevated to one of the high and solemn mysteries. There are actually colleges and institutions in the world to-day at which *you can receive instruction, and* win diplomas, in this art—the art of ascribing to an article virtues which it does not possess so persistently and so convincingly that ultimately you succeed in unloading it upon someone who does not want it. I speak with some feeling in the matter, because I myself am the possessor of, I think, 28 volumes, in half-morocco, *of an obsolete encyclopædia* which I was recently dragooned into buying, on the instalment system, by those exact methods.

From this you will realise that the whole aim of modern advertising, whether you are selling encyclo*pædias* or merely trying to get elected to Parliament, is to delude your hearers into confusing promise with performance; and the *odd* part about it is that the advertiser often ends by deluding himself. For instance, upon the promises of our most progressive railway companies you may possibly have observed pictorial posters depicting an express train, in three colours, *dashing along a* highly burnished permanent way at 70 miles an hour, supported by alliterative captions on the subject of *Sunny Southern Sunshine* Specials, or something of that kind. The railway companies in question obviously regard that poster as a perfectly adequate substitute for an efficient train service; and what is more, they can hypnotise some of their *passengers* into agreeing with them. We succumb to political wiles in the same fashion. One politician gets up and promises us *that he* will take a shilling off the income-tax. A second gets up and promises to make it two shillings; and so *fascinated* are we by the glamour of advertisement that we promptly vote for the second candidate, although we know perfectly well that neither of them has the slightest intention of taking anything off the income-tax at all.

So you see, if you want to get on in this world quickly you must advertise. And if you want to advertise *successfully*, the best way is to get into personal contact with your victim; and, of course, in personal contact it is your *bearing and* your manner which will count. Therefore, to be a successful man of business nowadays you must have personal magnetism or charm; and if you have not got charm you must acquire it—in other words, you must apply to persons who can sell it to you. And there are such persons. The other day I came across a most invaluable book, obviously of American origin, in which *was* set forth the whole art of making yourself attractive, and even lovable, to people to whom you want to sell something. In anticipation of my next interview with my publisher, somewhat overdue, I studied this little volume very carefully.

Personal Questions.

It started with a sort of *examination* paper, in which you were asked 40 questions about yourself, which you had to answer honestly and to the best *of* your ability, *and* then allot yourself marks for each. Here are a few. I pass them on to you, because I feel that it is not fair to keep such pearls to myself:—

1. Do you wear colours that are best suited to your type? If so, credit yourself with five marks.

2. Do you start to work every morning with clean finger-nails, clean boots, shaved, trousers pressed, suit and linen spotless? If so, credit yourself with five marks.

3. Can you walk across a room full of guests, speak to the hostess, and conduct yourself without awkwardness or embarrassment? If so, credit yourself with five marks.

4. Do you gesture from your shoulders instead of from your elbows? (See p. 135.)

Being entirely baffled by this question, I turned to p. 135, and discovered that to make gestures with your elbows is wrong, because if you do, "you do not include all the persons in a room." I had never known that. Anyhow, not knowing which part of my anatomy I do gesture with, I gave myself no marks and passed on.

5. Do you avoid using cheap, boastful expressions? Are you making some effort to improve your vocabulary? Do you own a good dictionary? If so, credit yourself with five marks.

I did not quite grasp the connexion between these questions, but I gave myself three marks. After all, *I do own a dictionary.*

6. Do you give a certain amount of thought in advance to your conversation with people you know you are to meet, so that you will be sure to talk of things that are of interest to them? *(See Chapter 7.)*

I looked up Chapter 7. It said :—

Here are some general questions with which to open a business conversation. Others, equally interesting, will occur to you.

(*a*) How far back can you remember?
(*b*) Do you fear death?
(*c*) How is your wireless working?
(*d*) How far do you consider you are indebted to your parents for all they have done for you?
(*e*) Do you think doctors should charge their patients in proportion to their incomes, or should they have a standard fee for their services?

I did not think that any of these topics would really interest my publisher, so I abandoned that chapter, and passed on to the seventh question.

7. Do you avoid making a public display of your affection for your wife or sweetheart?

I unhesitatingly credited myself with five more marks, and closed the book. There were 33 more questions, all as good as that, but I need not trouble you with further extracts. However, I think I have made it sufficiently clear to you what a complicated job it is in these days to fit yourself to be a really successful and lovable salesman.

THE ART OF HANDLING PATIENTS.

Still, at the back of all this rather fantastic stuff there is a real strain of common sense. Of course, it is of importance—enormous importance—to be able, on the top of all your intrinsic and technical merits, to suit yourself to your company and employ your natural gifts to their best advantage. And in the cultivation of the healing art—your art—I think you will admit that the human touch is of incalculable importance. I suppose it is true to say that as much healing is produced by suggestion as by physic, and that many a patient gets well simply because he believes in his doctor. We need not go all the way with Samuel Butler, who tells a story somewhere of a man who swallowed a doctor's prescription in the belief that it was actual medicine, and was immediately cured of a dangerous illness, but the human touch does count, all the time. A doctor is above all things a propagandist. To a certain extent he is always playing a part—backing up the resources of science by the arts of the skilled advocate; mixing the powder and the jam in such proportion that the powder escapes notice yet achieves its purpose; doing everything, in fact, that is morally justifiable to create, maintain, and increase the confidence of the patient in his own chances of speedy recovery.

This brings us to the real heart of our subject—the consideration of the gentle art of handling patients. I can say something about this, because, although I have never been a doctor, I have occasionally been a patient; and I agree with you, right away, that patients are a most unreasonable tribe of people. You can divide them into many classes, but three will suffice here :—

1. People who are really ill. We need say no more about these, because they give little or no trouble.

2. Patients who are rather ill, but do not believe in doctors, and tell you so quite frankly. You know the man who says to his doctor :—

"I only called you in because my wife insisted on it. I know as well as you do that the whole medical business is mere mumbo-jumbo, mere quackery; so don't start taking my blood pressure or doing any conjuring tricks with thermometers and stop-watches. I know how my inside works much better than you do, because it's my inside and not yours. You can leave me some medicine if you like, just to save your face; but I warn you I shall throw it out of the window."

That's the bluff, honest, hearty type of patient, the type that has made the name of Englishmen respected all over the world.

Well, the simplest and most profitable way to handle this individual is to employ the soft answer. You say :—

"My dear fellow, I agree with every word you utter. Of course, you are quite right; all medicine is nine parts faith and one part colouring matter. You and I both know that, so there is not the slightest use in my prescribing for you in the ordinary way. If I may say so, it is a treat to encounter a patient with whom a doctor can be absolutely frank—a patient who doesn't want things wrapped up in meaningless phrases. You, as of course you probably know without my telling you, are suffering from ——."

Here you give him the name of his disease in Latin—two longish words, with a false concord thrown in. You add a few scientific terms about reflexes and secretions, and so on, and wind up, if possible, with an incorrect chemical formula. After that, he will simply eat out of your hand. Technical terms are the medicine he wants. Many a man will positively enjoy a tennis elbow if he is allowed, when he talks about it at the club, to refer to it as "my synovitis."

Then we come to a third class of patient—the patient who thinks he is going to die forthwith, if not sooner, and has to be cheered up. In that connexion I cannot resist calling, or recalling, to your notice one of W. W. Jacobs's stories about that immortal trio Sam, Peter Russet, and Ginger Dick. I want to read you an extract. Sam, you may remember, was taken ill.

"And," continues the Night Watchman, who tells the story, "like most 'ealthy men who get a little something the matter with 'em, 'e made sure 'e was dying. 'E sent Peter out for a doctor, and in about 'arf an hour Peter came back with a sandy-'aired young man with red eyelids and a black bag. 'Am I dying, sir?' ses Sam, after the doctor had listened to his lungs and 'is 'art, and prodded 'im all over. 'We're all dying,' ses the doctor, 'only some of us 'll go sooner than others.' Peter and Ginger Dick took turns to be with Sam that morning, but in the arternoon the landlady's mother, an old lady who was almost as fat as Sam 'imself, came up to look arter 'im a bit. She sat on a chair by the side of 'is bed and tried to amuse 'im by telling 'im of all the death-beds she'd been at, and partikler of one man, the living image of Sam, who passed away in his sleep. It was past 10 o'clock when Peter and Ginger came 'ome, but they found poor Sam still awake and sitting up in bed propping 'is eyes open with 'is finger."

Well, that's a good example of how not to do it. What a patient of that kind wants is to be reassured; and that is where technical knowledge will not avail you so much as a cheerful presence and a confident manner. And here, speaking from my experience as a patient, may I drop a hint to future G.P.'s? Humanity fears one thing above all others—the unknown. What frightens a patient most of all is to have nothing definitely wrong with him. Once a definite cause has been assigned to his ailment, once you have hung a label on it marked in plain figures, and given him something physical to hold on to, he will endure almost anything. So if you can, be explicit with him upon this point, even though you may not have the slightest idea what is the matter with him. Tell him something—anything that will keep his imagination from soaring into the regions of unhealthy speculation. Anything will do: a man is never frightened of a thing he knows *all about*, or thinks he does. It is a good plan sometimes to be symbolic—to illustrate the patient's condition, or supposed condition, by some mechanical analogy. You can refer to trouble in his engine-room, or explain that his dynamo requires tuning up, or his accumulators recharging, or that an overstrained spring must be relaxed. Something tangible and concrete like that—something he can bite on. Tell him that he has a Rolls-Royce body, but that there is water in the carburettor, or the petrol pressure is faulty. That will cheer him up much more than to tell him baldly that his malady is functional and *not organic*. It is a strange thing, the amount of solid comfort a nervous person can derive from having his interior compared to that of a motor-car; but the comfort is there—especially if you tell him he's a Rolls-Royce.

THE SENSE OF RESPONSIBILITY.

Now, gentlemen, you must not think, because I am referring lightly at times to your responsibilities, that I do not realise very thoroughly how great and solemn those responsibilities will be. Yours, I suppose, is, with the possible exception of the teaching profession, the most responsible profession in the world. And for that reason you may be proud and thankful that you spring from the race you do, because our race possesses in a peculiar degree a quality which is indispensable to men of your calling—initiative; ability to act without running to someone else for instructions; readiness to assume responsibility as a mere matter of course. An Englishman possesses an extraordinary capacity for reliable work in a subordinate position, or perhaps I should say capacity to perform a task efficiently and conscientiously without any sort of supervision from higher up. Who are the men who keep the wheels of our Empire running? You may safely say they are not the people at the top. As a nation, we have seldom been well led or wisely directed in all our history. The main strength of our country lies, and always has lain, in our men-at-arms—our Other Ranks, as they call them in the army—whether those ranks be military or industrial, or administrative, or professional. Most of our successes, whether in war or peace, have been what we are proud to call soldiers' battles—the victories of the average man—the average Englishman. He is not brilliant, he is not spectacular, but you can rely on him. In South America they have a phrase, *Palabra Inglesa*—"on the word of an Englishman," and it means, with them, "Honour Bright!" That is the most splendid compliment ever paid by one nation to another, and it is addressed in the main to the man whom we are considering now. We ourselves depend on him to such an extent that we pay him the compliment of taking him as a matter of course—and we are seldom disappointed. The Civil servant, the platoon commander, the head clerk, the junior form master, the slum curate, the country doctor—these are they that propel the ship of State. Up above upon the quarter-deck, looking portentously wise and occasionally quarrelling for the possession of the helm, you may behold their superiors; but these friends of ours remain below the water-line—unheeded, uncredited, and to a large extent unsupervised, and that is the main point—and see to it that the wheels go round. They grumble and grouse, of course, and tell one another they are fed up—and usually they are—but they carry on, because initiative and responsibility are in their blood. They expect no thanks, and they are not disappointed. But the ship goes forward, and that is all they care about. Win or lose, sink or swim, in good times or in bad, that is what counts—the ship, the cause, the job, and not themselves.

Our Empire, like most of our institutions, came into existence in the most casual fashion. It was never acquired officially; it was never built up upon the ambitions or intrigues of kings and ministers. It was founded upon the efforts and sacrifices of common men—men whose very names have perished—who went out from our little island because the spirit of adventure bade them go out and better themselves, and who planted the seeds of enterprise and justice all over the world, to the complete effacement of themselves, and too often at the sacrifice of their own lives—men, in other words, who set the cause above the prize. It was only when through their efforts our interests in this quarter of the globe, or that, grew too unwieldy or important for private control that the British Government, with a deep sigh and an anxious eye on the taxpayer at home, reached out a reluctant hand and took official command.

To-day, all over the world wherever our flag flies, men you never heard of, and never will hear of, are shouldering responsibilities, making rapid decisions, improvising working expedients, getting the wheels round somehow—not for any special honour or glory that is going to accrue to them, but because it is their job, and it is up to them and them alone to do it. So they do it, by sheer force of character, personality, and the human touch. These are the things which bring them through. And foremost among those men I salute the members of your profession, because that profession bears as heavy and as proud a share of those burdens and those responsibilities as any.

THE FUTURE OF THE MEDICAL STUDENT.
